SKETCH OF THE LIVES AND OPINIONS OF THE CHIEF ALCHEMICAL AND CHEMICAL PHYSICIANS OR IATRO-CHEMISTS.

By M. DONOVAN, Esq., M.R.I.A.

AMONGST the causes which long retarded the improvement of the healing art, the superstitions of astrology and the delusions of alchemy occupied a prominent position. Both professed to confer extraordinary advantages, one contributing the prognosis of disease, and the other its cure. Neither fulfilled its promises; and for centuries, patients and physicians were deceived by fictitious science.

After a long and strong hold on the credulity of mankind, astrological medicine descended to its tomb, where we may be permitted to hope its ashes will never more be disturbed. But medicine was still embarrassed with a restless associate supported by advocates fully as powerful, as presumptuous in its objects, more energetic in its efforts, and not less delusory in its professions. Such was alchemy, an art which aspired at conferring on human nature all that seemed desirable to man. It professed to create wealth by transmuting worthless matter into gold, silver, and gems; and it promised health through the intervention of an universal medicine which was to cure all diseases and prolong life indefinitely. Could anything be more splendid if attainable? The secret of the philosopher's stone and panacea once divulged, no one would think of dying unless a few unreasonable beings whom nothing could satisfy.

At what time alchemy made its appearance in the world we are ignorant. In order to enhance its importance through the magnifying medium of antiquity, the adepts, dating their origin as far back as they could, pretended that their art was known to Adam and Noah; that it was diffused by the descendants of the latter after the deluge; that in Egypt, the nursery of all knowledge, it took root; was taught by the priests to Pythagoras during his residence amongst them, at his earnest and long-continued solicitation; and that by him it was brought to Europe. According to Zozimus, angels, enamoured of the daughters of men, in return for their favours, taught them how to make gold and silver.

The art was certainly cultivated in very remote times. It is with much hesitation that I submit the following considerations relative to a passage in the Apocalypse, which has been explained by competent persons in a very different manner. In ch. xxi., v. 20, in an enumeration of precious stones, is mentioned the chrysoprasus, which etymologists derive from χρυσὸς gold, and πράσον a scallion. Pliny says its colour resembles the juice of a scallion (porrum), but inclines a little to the colour of gold. We know that this naturalist was sometimes misled by his imagination: was his imagination, in this case, influenced by etymology: has any one a clear idea of a precious stone of the colour of scallion-juice inclining to gold: what could induce any nation to derive the colour of a precious stone from that of scallion-juice; but above all, to qualify it by a resemblance to the colour of gold, when the thing could be so easily expressed by some more familiar comparison? It appears to me that the word may be derived, not from πράσον, but from πρασσω, I make: it occurs in a list of precious stones: what can be more precious than that which makes gold—the gold-maker—the philosopher's stone. It is to be recollected that this pseudo-science of making gold is really very old, although not so old as is pretended by the alchemists. The transmutation of bodies by a change in their elementary matter was well understood in some of the ancient systems of philosophy; there is nothing improbable in supposing that the possibility of the most valuable of all transmutations had entered into the minds of men; and that a precious stone might be supposed to have some influence in effecting the change, just as in after ages the philosopher's stone was believed to be efficient for the same purpose. If there be any truth in all this, the first notions of alchemy might have been current in the time of that of St. John who wrote the Apocalypse: and we know that in two centuries after, the art of making gold had become quite a common pursuit in some parts of the world.

The conquests of the Arabians in the southern parts of

Europe made them acquainted with this pretended art; by them it was prosecuted with ardour, and many chemical compounds of real value were discovered. It was, in fact, alchemy that promoted chemistry; and the search after an imaginary universal medicine ended in the knowledge of particular remedies infinitely greater in value. The term alchemy first occurs during the reign of Constantine the Great; but the art itself was at that time pretty generally practised.

Some knowledge of the art of making gold was professed by the Greek ecclesiastics about the third century. That it had been much cultivated about the same period by the Egyptians is certain; the Emperor Dioclesian, after the sacking of Alexandria in the year 296, in order that the turbulent Egyptians might no longer, through the medium of the precious metals, have the means of resisting the power of the Roman empire, caused the books of the Egyptian sages on the art of making gold and silver to be carefully sought out, and burnt. The Romans, convinced that the making of gold and silver was a doubtful source of national prosperity, at length banished from Rome all persons pretending to the art of transmutation.

The first written record which we possess on the subject is a Greek manuscript by Zozimus of Panopolis in Egypt, entitled "Chrysopœia," supposed by some to be written in the fourth, by others in the fifth century; it was preserved in the royal library at Paris, and was entitled "The Divine Art of making Gold and Silver." Shortly after followed the treatise of Æneas of Gaza (A.D. 485), who affirmed that "such as are skilled in the ways of nature can take silver and tin, and changing their nature, turn them into gold."

In the fourth century also lived Jamblichus and Heliodorus, bishop of Tricea, who wrote a poetical treatise on alchemy still extant: and in the fifth, Olympiodorus and Synesius; all of them persons well known in the history of literature, who, however, misapplied their talents to the mysteries of transmutation. Synesius was a Greek abbot, afterwards bishop of Cyrene, a city of Libya, and was distinguished for his learning and piety: he was the *magnum lumen* of the alchemists of his time: was born in 365, and raised to the bishopric in 410. The work on alchemy attributed to him is no credit either to his candour or his understanding. Whosoever wishes a specimen of the allegorical jargon of the adepts who pretended to knowledge which never existed, dictated processes which could not be performed, and declared results which were out of the nature of things, let him read the learned bishop's book; and if there be a single step in his process for making the philosopher's stone which can be followed, or an important sentence in the whole book which can be clearly understood, then I have misrepresented the pious Synesius.

The first alchemistic physician of whom any account remains is Geber, a renowned character amongst the adepts. His history being in a great measure lost, the time when he lived is not now ascertainable, but the seventh century is supposed to be his era. It is said with probability that he was an Arabian physician; some say that he was an Arabian prince, others make him an Indian prince; but Leo Africanus maintains that he was a Greek christian who became a Mahometan. The alchemists affirm that he was the first who laboured at an universal medicine. Some suppose him to have been the discoverer of algebra; and Dr. Johnson derives the word "algebra" from the name Geber, as well as the very opposite word "gibberish," which he thinks alludes to the alchemistical jargon in which he indulged. He is said to have written five hundred volumes: his works now known are comprised in one small book.

Geber seems to have been an enthusiastic champion of his art, and to have entertained no very friendly sentiments for the sophisters who opposed it. In argument with them he is sufficiently laconic; to some he contents himself with merely asserting that they lie; on others he bestows a few hearty maledictions, and wishes "that they may be —— to all eternity." He declares that the mere thinking of their errors had brought on desperation and disturbed his reason, the latter of which positions the reader of Geber's book will probably be little inclined to doubt. His anticipations of his own fate are not more charitable; for he says he shall certainly be accursed if he does not correct the errors of these sophisters who deny his art; and adds, that their reasonings on the subject just amount to this argument—viz., "an ass runs, therefore thou art a goat." Speaking of the difficulty of imitating natural productions, he gives as an illustration, that "we know not how to form an ass;" a statement which comes badly from one that made so many. Yet, afterwards, he professes that "we are not ignorant how to form an ox or a goat in respect of composition." His arguments often tend to obscure rather than illustrate the subject; and sometimes, in pretending to give information, he discloses with solemnity what is puerile and self-evident. Thus, he says, "the grand question is from what things may mercury (the basis of gold) be extracted?" and he answers, "it must be taken from the things in which it is." This he considered an aphorism worth reporting. Geber, and all his successors, wrote in enigmatical language and half-expressed sentences. It was a kind of conventional jargon intended to be unintelligible to the mass of mankind, in order, as they said, to prevent their enemies and bad men from understanding their art. The most dreadful punishments were denounced against those who divulged, to the impious, secrets intended by Providence only for the comprehension of the faithful—an idea, no doubt, borrowed from the Eleusinian Mysteries. In their endeavours to disguise their art, they seem to have fully succeeded, as their writings are alike incomprehensible to friend and foe. I have read the work of Geber throughout, and can declare that in the alchemical portion I did not meet a fact worth knowing, nor an intelligible point of doctrine. His notion was, that all metals are compounds of mercury and sulphur, pure or impure; if impure, we have *merely* to remove the impurity, and the metal is changed into gold or silver. The substance that removes the impurity he calls its medicine; and he gives a process for preparing it for each of the metals. One of the ingredients is sal-ammoniac, which he prepares by mixing five parts of man's urine, one part of his sweat, one of common salt, and half a part of wood-soot; these are to be boiled to dryness, and sublimed. Gold made from this sal-ammoniac would be ten times more costly than common gold, were the fabrication of it even practicable.

The medicine necessary for converting mercury into silver is thus prepared:—Take nitrate of silver, white arsenic, precipitated sulphur, saltpetre, and sal-ammoniac; grind, and heat them in a flask for a week; take them out, and incinerate a third time. This is the ferment. Take as much as before of new matter, and join it with this ferment, and do so as before a third and fourth time. Of the resulting substance, one part will convert ten of mercury into true silver (page 266). Yet some have affirmed that Geber was not an alchemist. Geber is considered the first that laboured at the universal medicine, yet there seems reason to believe that the idea was old even in his day. More than a thousand years before the time of Geber, we find Empedocles thus speaking of himself:—"By my instructions you shall learn medicines that are powerful to cure disease and reanimate old age. . . . You shall recall the strength of the dead man when he has already become the victim of Pluto." Nay, he says, that he is followed by tens of thousands of persons "inquiring the road to boundless wealth," as if he claimed a knowledge of alchemy.

This Empedocles was an eminent physician and philosopher of Agrigentum, in Sicily, who flourished about four centuries and a half before the Christian era. We may infer that his reputation as a physician was high by the story told of his restoring to life a woman who had been dead many years; a feat also performed by Appollonius Tyanæus, who lived in the time of our Saviour, and whose miracles have been compared by some profane writers with those of the Son of God.

From the time of Geber, a number of alchemistical phy-

sicians appeared, but we may pass them by in order to notice the most celebrated of them all. Albertus Magnus was born in Lawingen in 1205, or, as some say, in 1193, and although in early life he was dull and backward in his learning, he afterwards became remarkable for his acquirements in theology, philosophy, and medicine. He was the most celebrated of all the alchemistical physicians. He gave lectures on the foregoing subjects to such numbers of pupils that no building could be found large enough to contain them, so that he was obliged to address them in the open air. Although a physician, he was at length created Bishop of Ratisbon, as Henry II. of England had a few years before consecrated his apothecary a bishop; and soon after, at the desire of Pope Alexander IV., he undertook to preach in favour of the crusades. Amongst those who were incapable of appreciating his real acquirements, he obtained credit for knowledge which he did not possess; hence he was deemed a magician, and wonderful stories are recounted of his feats and his cures. It is said that he constructed a brazen figure of a human being which spoke distinctly, and performed the useful office of opening the door for those that knocked. The conversational powers of the man of brass at length increased to so troublesome a degree, that in order to stop his talk he was broken to pieces by Thomas Aquinas, the pupil of Albertus, whose studies were disturbed by his loquacity.

Amongst other surprising acts, it is related of Albertus that he entertained William Count of Holland with a supper in the open air when the country was covered with snow. On a sudden the snow vanished, the sun shone, the air became genial, flowers sprang up, birds sang, and the trees blossomed. After supper, at the command of the magician, winter in all its rigors returned. Dark indeed must have been the age when such fables were endured.

Albert the Great descended to the grave at the age of 75, laden with honours and rewards. How different the fate of his contemporary, the unfortunate Roger Bacon, a kindred but superior genius, whose vast resources of mind, invention, and learning, shamed the age in which he lived. Persecuted and incarcerated as a necromancer having communion with devils, he bowed to his fate, the victim of oppression and neglected genius (1214 to 1292).

The works of Albertus were printed at Lyons, 1651, in twenty-one volumes folio. He wrote much on mathematics, but made no discoveries; he also wrote a treatise on natural history, but his most curious work is that on alchemy, which gives a complete view of the state of chemistry at the time. In this he affirms that there are different kinds of the philosopher's stone: a doctrine which had excited great sensation amongst the alchemists. It does not appear that he claimed to have effected any considerable transmutation.

But any deficiency in this respect was amply compensated by the wholesale transmutations of a brother church dignitary, his contemporary. This was no less than the Pontiff John XXII., one of the popes of Avignon, born in 1244, who wrote a work on alchemy; in the preface of which he informs his readers that he had made two hundred ingots of gold at Avignon, each of which weighed a quintal; yet when elevated to the papal chair in 1316, he issued a bull in which he denounces alchemy as a fraud, and condemns all persons, whether lay or clerical, who make gold or procure others to make it. It is said that after this pope's death, in 1344. no less than thirteen millions of florins, and seven millions in other value, were found in his treasury. The opinion at the time was, that this wealth was the produce of his alchemical labours. Platina admits that an immense quantity of gold was found; but Kircher denies that it was obtained by art. It was probably, as Hallam observes, the proceeds of the first fruits of ecclesiastical benefices: a tax which this insatiate pontiff established for his own benefit.

During the reign of Edward I. (1272 to 1307), who was contemporary with Pope John XXII., a remarkable transmutation is said to have been effected at the Tower of London, in the presence of the sovereign, by the celebrated Raymund Lully. This remarkable person was born in 1234, in the island of Majorca. In his early days he engaged in the service of the King of Arragon, but disgusted with the licentiousness of a military life, in which, however, he had at first freely indulged, he left the army, retired to a desert, and became a hermit. Here he had a vision, in which he believed himself called by the Saviour to undertake the conversion of the Mahometans; he therefore applied himself to study, undertook his mission, incurred various dangers during its progress, which, however, were insufficient to turn him from his purpose; he persevered with exemplary assiduity, until at length, after various unsuccessful attempts, he was stoned to death at Bugia (1315), in the 81st year of his age, by the enraged Mahometans.

He was a person of uncommon energy and perseverance; his acquirements were extensive and diversified; there were an earnestness and honesty of purpose in his efforts for the propagation of his faith, which did more credit to his heart than his head, considering the rashness of the enterprise. But all his virtues and accomplishments do not countervail the deception which he practised on the world. He professed to make gold, and being invited to England by King Edward I., he was lodged in the Tower of London, where it is said he made a quantity of gold, which was actually coined at the Mint into six millions of rose-nobles. In his last testament, Lully declares that at one turn he transmuted 50,000 pounds of mercury, lead, and tin into gold! One would incline to imagine that he believed the story.

A romantic, beautiful, and moral story is told of his love for a virtuous married lady, who, after ineffectually endeavouring to repress his unlawful ardour, succeeded by displaying her bosom, so much the object of his desires, eroded by a frightful cancerous ulceration.

Arnold Villanova, a Milanese, born 1245, lived at the same time with Raymund Lully, and instructed him in the hermetic art. Arnold was an excellent Greek, Hebrew, and Arabic scholar, and spent much of his life travelling in pursuit of knowledge. He studied medicine at Paris during twenty years, and ten at Montpelier; and for his knowledge of medicine and astrology was held in such estimation that a sect appeared under the title of Arnoldistæ. He wrote treatises on medicine, chemistry, and theology, and was considered one of the most able disputants of his age. While at Rome, he is reported to have transmuted iron bars into gold, which stood every test of its purity. Beside being a theologian, a physician, and an alchemist, he was an astrologer, and prophesied that the end of the world was to take place in 1335: a prediction which he lived to see falsified. Eminent attainments in a highly ignorant age generally drew on the possessor the imputation of practising the diabolical art; Arnold was accordingly cited before the Inquisition, but contrived to escape punishment. Having reflected on the monks, their hostility was excited against him; the faculty of theology in Paris condemned his opinions as heretical, and he was obliged to leave Paris. Yet such was the estimation in which his medical knowledge was held, that after his death a circular was issued by Pope Clement, adjuring every one under their apostolical obedience to search out and discover a treatise on medicine undertaken by him, and intended as a present to the Pope. Arnold died in 1313, aged 73.

The gold supplied to the treasury of Edward I., by Raymond Lully, which that enthusiastic alchemist stipulated should be expended on the conversion of the Mahometans, but which the prudent monarch thought would be better employed at home, seems to have given a taste to the English government for raising supplies in this independent and summary way. In 1329 the following proclamation was issued by King Edward III.:—"Know all men that we have been assured that John Rows and Mr. William de Dalby, know how to make silver by the art of alchemy; that they have made it in former times, and still continue to make it; and considering that these men by

their art, and by making that precious metal may be profitable to us and to our kingdom, we have commanded our well-beloved Thomas Cary to apprehend the foresaid John and William, wherever they can be found within liberties or without, and bring them to us, together with all the instruments of their art under safe and sure custody."

In progress of time so infatuated did the nobility and gentry become by the glittering promises of alchemy that fortunes were ruined and passed into the hands of knaves and impostors with which the world abounded. The story of the unfortunate Bernard-Georges Penot is still remembered, although the salutary lesson which it afforded was at the time unheeded. This wretched enthusiast, after expending vast sums in the pursuit of the philosopher's stone, too late discovered his folly, and strove to warn the infatuated against a delusion which left him on his death bed a miserable inmate of an hospital.

The interposition of the law becoming necessary, an act of parliament, passed in 1404, during the reign of Henry IV., which provided, that "none from henceforth shall use to multiply gold and silver, or use the craft of multiplication, and if any the same do, he shall incur the pain of felony." Yet such are the vicissitudes of public opinion that about the middle of the same century, during the reign of Henry VI. (1455), the transmutation of metals and the search after the universal medicine were permitted by patent to be exercised by particular persons, in order to enable the king to pay off the debts of the crown in real gold and silver, although the original statute remained in force and was not repealed until 1689. It is said that this legislative prohibition of alchemy did not originate so much in the universal panic which the ruin of so many noble fortunes occasioned, as in an apprehension lest government should be made independent of the supplies voted by the nation. The case has been thus stated:—"After Raymond Lully and Sir George Ripley had so largely multiplied gold, the lords and commons conceiving some danger that the regency, having such immense treasure at command, would be above asking aid of the subject, and might become too arbitrary and tyrannical, made an act against multiplying gold and silver." It may be mentioned here that this Sir George Ripley was canon of Bredlington, and an alchemist of high repute, who wrote a treatise on alchemy in verse. He is reported to have furnished £100,000 to support the war carried on by the Knights of Rhodes against the Turks.

At this time—namely, the fifteenth century, the world teemed with alchemists and their works. The Bibliotheca Chymica, a century later, contains an account of no less than 4,000 writers on alchemy. In almost all the sovereign courts of Germany there was a state alchemist associated with the state physician; and even kings themselves condescended to the operations of the crucible and furnace.

A ludicrous and characteristic story is told of the treatment of an Italian adept named Augurelli (born 1441) by Pope Leo X., which, if acted on universally, would have extinguished this kind of imposture. Augurelli not content with mere knowledge of the process of making gold, wished to convert his skill to more certain and immediate account. He therefore wrote a poetical eulogy on its value, and a description of the process. He called this effort of his muse "Chrysopœia," and dedicated it to the Pope. His Holiness, willing to confer on the poet an appropriate and equally valuable consideration, presented him with an empty purse, with this remark, "that as he could make gold, all he wanted was a purse to keep it in."

One of the most useful of the alchemists was Basil Valentine, born about the year 1394, who, although not originally destined for the profession of medicine, devoted himself to the study of it for reasons which he describes. He says that while he mixed with society he found that there was little repentance amongst men for their sins, and that they continually grew worse; he therefore bade farewell to the world, and became a Benedictine monk. In the monastery there was a monk troubled with a stone in the bladder, and as he obtained no relief from physicians, Basil applied himself to the experimental study of vegetables and minerals with a view of discovering a mode of relief for his distressed brother, and at length, as he says, succeeded. Hence arose his knowledge, and such was his progress that he declares he never failed to cure any patient he undertook. During his researches he made those famous experiments on antimony which led to the publication of his "Currus Triumphalis Antimonii," originally written in German, but soon translated into Latin and other languages. It is a curious admixture of allegory, jargon, piety, slander, anger, and falsehood, along with a valuable collection of facts and processes.

Basil seems to have entertained no great respect for the opinions and habits of the physicians of his day; he says "they know not whether their medicines be hot or dry, black or white; they only know them as written in their books, and seek after nothing but money. Labour is tedious to them, and they commit all to chance: they have no conscience: they write long scrolls of prescriptions, and the apothecary thumps their medicines in his mortar and the health out of the patient."

Elsewhere he gives us further insight into the state of the profession: "in times past (he says) long before my days, the doctors of medicine did themselves cure external wounds, and judged that a part of their office: but in these our times they take servants whom they employ in these things, and in this way the noblest of arts is become a mechanic operation; and some of those who exercise it are indeed so very rude that they know not letters, and scarcely know how to drive an ass out of the corn." Basil, then alluding to the ignorance of physicians with regard to surgery, says, they have as much knowledge of the cure of wounds "as is in the brain of a dunghill cock." He then concludes with this splendid apostrophe:—"Ye titled doctors who write long scrolls: ye apothecaries who fill pots with your decoctions as large as soup-pots that would feed some hundreds of men, blind as ye are, let me drop a collyrium into your eyes."

Amongst the wonders of his book one is a process for preparing the philosopher's stone; but as it is utterly unintelligible, it is quite safe in him to promise that, *when* procured, it produces riches, power, honour, and might: it also cures all diseases. It is made from gold; and one part of it, mixed with many thousand parts of any other metal, converts the whole into gold.

This worthy monk, himself living under vows of chastity, invented a variety of medicines, some of them for no very creditable purpose. Of his medicines he affirms they "are a sure remedy in almost any distemper." His manuscript works he concealed under a marble table behind the altar in the cathedral of Erfurt: or, as others say, behind a pillar, where they remained until the pillar was shattered by a flash of lightning.

The impostures of the alchemists were ingeniously contrived. One method of deceiving the observer into the belief of transmutation was to put a quantity of oxide of gold into the bottom of the crucible, covering the surface with a false bottom of coloured wax, or a very thin layer of crucible dust and solution of gum to imitate the real bottom: over the false bottom were placed various deceptive ingredients. When a sufficient heat was applied, the gold was reduced, and melted, while the crucible dust broke down into apparent scoriæ. Or a piece of gold was whitened with mercury, so that it looked like silver: this was put into the crucible along with the philosopher's stone, and the whole being heated, the mercury was volatilized, and the melted gold was exhibited to the admiring beholders. The method practised by Sendovogius was to plate a piece of gold with silver, and to immerse it in the elixir which he professed to have made, but which no doubt was disguised dilute nitric acid: the silver was dissolved away from the surface, and the gold left untouched: or he stirred mercury and other volatile ingredients with an iron rod containing gold in a hollow, and retained there by means of wax.

It is astonishing to think with what profound art these professed transmutations were effected, so much so as to deceive the most wary and intelligent in a manner never since explained. In the year 1710, an alchemist named Delisle, who had been a blacksmith, made gold out of lead and iron by means of an oil and a powder, some of which he gave to persons not interested in deception, who succeeded equally. The bishop of Senez wrote to the Comptroller-General of the Treasury at Paris that, being incredulous, he took every precaution against being deceived by Delisle; but that he could not resist the evidence of his senses. The Master of the Mint at Lyons wrote a certificate that he saw Delisle distil an oil, two drops of which poured on three ounces of hot mercury converted it into gold, which was presented to the Minister of State; and also that three ounces of pistol bullets being melted, Delisle handed the Master of the Mint a powder, desiring him to project a pinch of it on the lead with two drops of the oil, which, being done, the lead was found converted into gold of such purity that it stood the test of assay. This gold was coined into medals bearing the inscription "Aurum arte factum," some of which still exist in the Museum of Versailles. His reward eventually was committal to the Bastile, on his way to which he was wounded by a soldier, and at length died of the wound.

In 1620, gold was made from base metal before Gustavus Adolphus, and coined into medals bearing the king's effigy, and on the reverse, Mercury and Venus: it is even said that the king himself made gold, from which ducats were coined. A transmutation was also performed before the King of Prussia, when every precaution against imposture was apparently taken. In 1715, a transmutation was effected before Frederick Augustus, Duke of Saxony, by an apothecary, who, when his powder of projection was exhausted, was condemned to death, and only escaped by offering to make delph equal to china: he succeeded in his attempt, and thus laid the foundation of the Dresden manufactories. The elder Helvetius converted lead into gold before the Prince of Orange.

The great transmutation in the Tower of London, before Edward I., the gold resulting from which was coined into rose-nobles, has been already alluded to.

To possess the secret of transmutation was not without danger, and several persons suffered severely by their being supposed to have the means of doing so much injury to the landed and commercial interests. Lully was actually a prisoner in the Tower, and escaped from it. Thomas Dalton, who was said to have made a thousand pounds of good gold, was imprisoned, and threatened, if he did not disclose, with the loss of his head.

(To be continued.)

MEDICAL SOCIETY OF LONDON.—May 31.

Dr. Murphy, President.

Dr. Tilt read a communication

ON THE GALVANIC CATAPLASMS OF PROFESSOR RECAMIER.

After some preliminary observations, Dr. Tilt stated that he wished to draw the attention of the society to the particular mode of employing electricity, in which continued currents are generated by the contact of metals, by which means a large quantity of electricity is obtained at a low tension.

There are many machines constructed on that principle; but they are all ponderous complicated machines, liable to get out of order, and therefore requiring the guidance of some one who well understands their action. The feelings of awe, too, with which the patient generally beholds them, interfere frequently with the effects we desire to obtain. Would not, then, a milder application of the same agency, by permitting its prolonged employment, enable us to do more good than could be effected by the previously employed energetic modes of application? This simple question must have suggested itself to many, and it has suggested itself to a fellow of this society who has given great attention to the therapeutical influence of electricity. "I was very sanguine (says Dr. Golding Bird) that the current excited by a simple pair of zinc and silver plates, similar to those we employ to excite the contractions in a frog, would be found of great value in practice." But, to obtain an action, Dr. G. Bird thought it necessary to remove the cuticle from the skin; and then he found that the most oxidisable of the two metals produced sloughing of the skin, or in other words, the electrical moxa of which he had shown the utility.

Previously to this, Mr. Spencer Wells had ascertained that the removal of the cuticle is not necessary; and that, by applying to the skin, previously moistened by diluted vinegar, two plates, one of silver and the other of zinc, connected by a silver wire, a marked electrical action was obtained; disordered functions of a particular nerve were restored to their normal state, and ulcerated surfaces were rapidly healed.

For many years Professor Recamier had made use of electricity by means of the energetic apparatus usually employed; and it may perhaps be remembered that a few months ago, he presented to the French Academie de Médecine some remarks on a new mode of supplying electricity by what he called galvanic cataplasms, consisting of filings of copper and zinc enveloped in cotton wool. Lately he had improved on this rather clumsy contrivance, and he had sent Dr. Tilt the little apparatus which he had now the honour of submitting to the inspection of the fellows. Each of these cataplasms, or disks, if a scientific term was preferred, is a galvanic pile composed of twelve couples. The couple is formed by a riband of zinc and copper, and each couple is separated by a piece of flannel. On the coloured side is cotton wool; on the other, a piece of gutta percha tissue to insulate the apparatus. The only difference between the two disks is, that, in the pink one, the copper stands first, while the zinc comes first in the one covered with blue. The electrical force generated in the apparatus is sent through the copper rings, to which the insulated copper wire can be attached when the more energetic effect of the two cataplasms is required. In some people the acid perspiration of the skin is sufficient to increase the intensity of the electric action; but more active effects are produced by wetting the flannels with diluted vinegar, or a weak solution of common salt, as is seen by the action of the apparatus on the electrometer. When one of these cataplasms is tightly bound to the surface on the skin, it gives an unusual sensation of warmth,—a pricking sensation is felt, and the skin is made red; and, when two of the cataplasms are connected by the wire, and applied to the same surface, but at some distance from one another. A stronger effect is produced when one is applied to the organ we wish to influence, and another to the opposite portion of the spine. Such are the modes of application; and it may be worn day and night without inconvenience, though, in ordinary cases, it is only under application at night. In what cases this apparatus has been, or may be expected to be useful, is a question which now naturally suggests itself. In the hands of Professor Recamier, it once brought on menstruation before the usual time. He therefore intentionally applied it for that purpose, and with success, in cases of chlorotic amenorrhœa. He is trying it in such cases of sterility as cannot be accounted for by any disease, but which seems to depend on a defective ovarian action; and, amongst other cases, on an illustrious lady, whose barrenness menaces to extinguish one of the oldest dynasties of Europe, and also in the case of a Russian princess. In this last case, menstruation, which formerly lasted but thirty-six hours, now continues for six days. This is the first effect; but time alone can show whether sterility will be removed in this or the other cases. Dr. Tilt thought it would help to cure some of those tedious cases of chlorosis where a girl eats heartily, takes plenty of sleep and exercise, has nothing on her mind, and still derives but little benefit from good food and judicious treatment. In hopes that this mild electric action may take effect on the ganglionic nervous system, and give a spur to defective nutrition, he has

lately applied one of the disks to the epigastric region of a patient, and the other to the spine. Besides these trials, Professor Recamier has applied these galvanic cataplasms, with marked and rapid success, in the treatment of rheumatic and nervous pains; in one obstinate case of constipation of some years standing; in a case of asthma; and a patient suffering from angina pectoris was benefited, but not cured. Dr. Massé, and several other medical men in Paris, have found them successful in similar cases, as you will see by perusing the pamphlet Dr. Tilt presented to the society. In this communication he has merely stated the results said to have been obtained by his venerable teacher; and, if this had not been the last meeting of the society, he would have delayed drawing the attention of the society to the subject until he had been able to test its utility by his own observations. He thought, however, the matter sufficiently deserving of consideration; and if, on account of the harmless appearance of the apparatus, the fellows should be tempted to consider it ineffectual, he would beg to refer them to an authority already quoted, who says—"From what I have seen, I am fully convinced that a feeble current, if kept up for a long time in certain forms of paralysis (care being taken that the positive fluid traverses the limb in the direction of the nerves), would prove the most important mode of applying this remedy with success." It seemed to Dr. Tilt that Prof. Recamier's cataplasms would be useful; and, as it was impossible for the fellows to give them a trial without knowing where to get them, he concluded by informing them that the apparatus might be obtained of Mr. Joseau of the Haymarket, or of Mr. Bucklee of 86, New Bond-street, Oxford-street, at the cost of 15*s*.

PHARMACEUTICAL SOCIETY.—May 20.

Mr. William Ince, President, in the chair.

ADDRESS OF THE PRESIDENT.

I appear before you as the representative of the council, elected by yourselves to carry on the affairs of the Pharmaceutical Society of Great Britain. You did me the honour last year of returning me one of your council, which by lot will extend to another year. Your council proposing me as their president, I reluctantly accepted it; that reluctance arising from a sense of my own inability to do the office justice. my health not being so firm as I could wish. However, I am now here, as you see, to render an account of our stewardship. I have but little to say by way of preliminary observations to the report which will be read to you, and which it will be your duty to scan and criticise. We are very desirous that you should know all our affairs; we desire to withhold no information; and most gladly shall we listen to any remarks which may have reference to the future prosperity of the society. Before I go to the subject of the report, allow me to offer some general observations on pharmacy and its progress. It does not fall to my lot to introduce to your notice any new remedies of importance, which the genius of pharmaceutists has presented to medical science during the past year.

Some of those previously in use, however, have acquired increased reputation, while others seem destined for a less favourable result. You have cod-liver oil now in large consumption, employing considerable capital—equally beneficial to the diseased and profitable to the dispenser. Strychnine, in its various forms, is extensively employed in medicine; and, I am now informed, is used in astonishing quantities in the destruction of fur-bearing animals, the skins being less injured by this process of destroying life than some others. Chloroform increases in reputation. Cotyledon and kousso, I fear, will not stand the test of experience. The extravagant price of the latter reminds one of the recommendation of the medical man to his patient to go to Madeira, or take horse exercise, when in fact the patient had not the means to buy his daily bread. The compounds of valerianic acid are interesting, and no doubt some of them will be found to be valuable remedial agents. The salts of iron, with citric acid, ammonia, and quinine, have a continued demand.

As to our influence, we may mention the Sale of Arsenic Bill, now before the legislature, the enactments of which will not very much interfere with us. It is denuded, we think, of all mischief by the exertions of the previous examination which had been given to the subject by our committee.

I have to notice the issue of two new Pharmacopœias since our last anniversary: the one from Dublin, and the other from the Royal College of Physicians of London—to whose high privileges we most submissively bow. These Pharmacopœias are great improvements upon their predecessors; they show much advancement in a right direction, but it is deeply to be regretted that the London College, whom we are called upon to follow, should not have called to their assistance a few well-known chemists and druggists, whose long experience and extensive knowledge in practical pharmacy would have guaranteed them from some of the errors and inconsistencies which are so palpable in their last production. In this department, it cannot be doubted that men, whose every-day employment is the compounding of medicine and the improvement of pharmacy, have vastly the advantage over professional men whose time is almost exclusively occupied in the investigation of disease.

I am glad that translators and commentators of pharmacopœias are appearing from our own body. One of our former presidents announces a work on the subject, and our esteemed and valuable Professor of Pharmacy, another. I am sorry to know that Mr. R. Phillips, for many years past the able translator and annotator of the London Pharmacopœia, is no longer amongst the living: he died last week, the day before the formal opening of the Museum of Practical Geology, of which he was the distinguished scientific secretary or curator. You are aware he was originally a chemist in the Poultry. The glaring errors of the new Pharmacopœia of that day called forth from his pen a very able and acute critique on that work, in a pamphlet entitled "Some Observations on certain Preparations of the New London Pharmacopœia." I believe the remarks were so generally correct as to acquire for him great praise, and entitle him to rank as an able chemist. The college had to surrender at discretion, and ultimately chose him as their adviser.

It has given me great pleasure also to find many of our members diligently employed in duties connected with the benefit of the country, especially in the sanitary movements now so loudly demanded. I must mention the names of Mr. Liddell of Hull, formerly a London chemist, and Mr. Dakin of London, formerly one of your council.

And now will you allow me to travel back to the Pharmaceutical Society. The sittings of council, I can assure you, have been well attended: with one exception we have had a full board of generally twenty members. Our labours have not been slight; many have been the discussions; and although we have not been agreed upon some subjects (for uniformity would be dreadfully dull), yet we have always thought it right to carry out the principles of the majority in their full integrity. I need not disguise that which I have reason to believe is well known to some of you at least, that I have not unfrequently been in the minority. I may be forgiven if, for this once, I tell you that I have watched carefully the interests of this society from its commencement. I had no selfish motive to join with it. I think if I had to draw a balance it would be against me, except your favour. We sprang up into existence under the influence of threatened wrong and oppression, speedily became a powerfully united body, and then trammelled ourselves with a charter before we were quite certain what were our requirements. Under these circumstances it is not to be wondered at that everything was not altogether so representative as we could desire. I could have wished the election of council to have been in the whole body of members; the power to vote, in London, personally only; five miles from London, by post. This, I think, would have made us more united. One-

third of the council should have remained by rotation, not by lot. The secretary, and probably the professor, should have been the choice of the whole body.

I have some settled opinions with reference to the society, and you must bear with my stating them this once. One point to which I allude is that on which many of the members, in conjunction with others, memorialized the council, having reference to the Transactions of the Society and the Journal, in which they are distributed at the cost and charge of our funds. Another is the secretarial department. I am thoroughly persuaded in my own mind that no learned society or body can take rank, or station, or influence, or increase in numbers, except it has a secretary devoted entirely to its service, who, from education and scientific knowledge, is equal to take the lead in every department, and to be always available. The business of accounts, taking minutes, keeping books, carrying on ordinary correspondence, is very good and proper, and is very well done by your present secretary, who I trust will not misunderstand me in these observations, which do not detract from his services. The next notion I have is, that we are fettered in our house. It was a mistake to be here without out-door premises for laboratory purposes, for we are seriously crippled for want of space to extend our operations. Already our museum has outgrown the room devoted to it, and the secretary has ceased to have residence in the house.

The last opinion I shall mention is that with reference to our legal standing. We have made no real advance yet. Have our efforts been in the right direction? The chemist and druggist of the present day originated really fifty or sixty years ago, not much earlier. A few apothecaries, disliking to have the annoyance of being roused from their beds and boards, contrived to draw all their practice to their own little shops, and in course of time they became the retailers of physic without visiting the patients; by degrees the public began to approve of the plan, and the retailer also improved the quality of his physic, having more employment for it; moreover, enlightenment with reference to the nature and quality of drugs, opened the way to the public attempting to doctor themselves. In process of time, they required the experience of the dealer of physic to be added to the physic itself. It soon appeared desirable to take the superior medical man's advice upon paper, and thus, to a great extent, the status of the intermediate visiting apothecary was altered. The public, always alive to their own interests, saw it worked well—in fact, it was a step towards free trade. Many rushed into the new-created order; and now the chemist and druggist is expected to be always ready with his choice stock of effective drugs, and able to prepare with great accuracy the prescriptions and recipes of the medical advisers who no longer supply the medicines. From the chemist and druggist is also expected, in minor cases of disease, that relief which it is believed he can without danger give. An immense amount of good is thus effected, and much bodily suffering spared; and although it may be true that in some cases a more accurate knowledge would have deterred him from interfering, yet the trifling mischief thus effected is so completely counterbalanced by the enormous benefit conferred, that any attempt to cripple the chemist and druggist would crowd the houses of parliament with petitions in his favour. Hence legislative interference can only go in one direction—that of requiring qualification from those who call themselves chemists and druggists. . . . . .

On taking a review of the history of the society from its formation up to the present time, and comparing the previous position of the pharmaceutical chemists of this country with that which they have now acquired, the council feel assured that an important advance has been made, creditable to the promoters of the movement, and beneficial to the public.

Although the sanguine hopes of some of the founders, in regard to the sanction of the legislature, have not yet been realized, the influence of the society has been extended, and its character has been raised, by the successful efforts which have been made to promote pharmaceutical advancement, and establish a system of education. The council may congratulate the members on the comparative freedom they have lately enjoyed from those attacks and hostilities which were prevalent in former years, and which in fact were instrumental in calling the society into existence, by demonstrating the necessity of union for self-defence. The maintenance of a representative body ready to act promptly in case of any emergency arising, in which the general interests are concerned, is in itself of no small importance. But the chief weight and influence enjoyed by the society arises from the fact, that qualification has now become the basis of membership; and that during each succeeding year the ranks are reinforced with pharmaceutical chemists, who have gone through a regular course of study, and substantiated their claims to the confidence of the public by passing an examination. It cannot be doubted that this professional improvement would have been more rapid and more general, if the measures adopted for its promotion had been under the sanction of the legislature, but the maintenance of such an institution by voluntary means, at considerable expense, during a period of ten years, is a circumstance reflecting more credit on the zeal and sincerity of its supporters, than could have been conferred by even a wider field of success under the compulsory provisions of an act of parliament.

ON THE TREATMENT OF STRICTURE BY EXTERNAL INCISION.

By James Syme, Esq.,
Professor of Clinical Surgery in the University of Edinburgh.

Strictures of the urethra may be divided into three classes: First, those in which there is no real organic contraction of the canal; second, those in which the contraction admits of dilatation, and may be prevented from returning by the use of bougies; and thirdly, those which either resist attempts to effect dilatation, or return so quickly after its completion as to prevent any permanent advantage from being derived by the patient.

The first class is very numerous, in consequence of the various and frequent circumstances which, independently of contraction, tend to impede the flow of urine. Hæmorrhoidal affections, and fissure of the anus, enlargement of the prostate, paralytic states of the bladder, disorder of the digestive organs, sexual excesses, and an irritable state of the urethra, with many other derangements of a functional and organic kind that might be mentioned, are apt to occasion, more or less, uneasiness in micturition, and excite the suspicion of stricture. The introduction of a full-sized bougie would of course correct any such erroneous impression, but unfortunately cannot always be accomplished, even though there is no obstruction, through want of practice in the use of instruments, and morbid sensibility on the part of the patient. Both he and the practitioner are thus apt to be confirmed in their mistake, and led to enter upon a course of treatment not only altogether unnecessary, but frequently very injurious. It is in these imaginary strictures that various means of remedy have acquired any credit they possess, such as of course all those employed externally, or through the medium of the system; and also many others of a local kind, which could not be mentioned on the present occasion without giving offence to their respective authors or advocates, and therefore may be passed over in silence, since they never can be of any practical utility *to the patient*. At the same time, I think it right to protest openly and distinctly against any evidence drawn from this spurious source, being admitted into the discussion of what may be done with most advantage for the treatment of real organic stricture.

The dilatable form of this disease may be remedied in many different ways, through the use of bougies and catheters, flexible or rigid, and introduced occasionally, or retained permanently during the period of treatment. While it cannot be denied that the object in view may be attained by any of these modes, there is as little doubt that they

cannot be all equally beneficial, or free from inconvenience; and when they are compared together, with regard to their qualities in these respects, I think there should be no hesitation in giving a decided preference to the metallic bougie, employed at intervals of from two to four days, and withdrawn each time immediately after being introduced. This method, which has been characterised by one of the London writers as "*frivolous*," affords the certain means of dilating any dilatable stricture in the course of a few weeks, not only more easily and safely than any of the other forms in which pressure is employed to widen contractions of the urethra, but also with a greater degree of lasting effect, since it appears that the more slowly the process of dilatation is accomplished, the less rapid is subsequent relapse.

The third sort of stricture fortunately bears a small proportion in frequency to the one last mentioned, but does not do so to the same extent at all parts of the urethra. It is between two and three inches from the orifice, and just before the bulb, that organic contractions are chiefly met with. Tight strictures are much more frequent in the latter than the former of these situations, but when they do occur in the anterior part of the canal, are more apt to prove obstinate than those of the posterior position. Thus, of twelve tight strictures, the proportion may be about three in the anterior, and nine in the posterior situation, and in each of them *one* of the obstinate kind. I happen to have in my possession a letter from the late Mr. John Pearson of London, to the late Dr. John Thomson of Edinburgh, which affords a remarkable illustration of this pathological fact in the following extract:—

London, September 26, 1804.

I have lately had under my care a case of impermeable stricture, about two inches from the meatus urinæ. Being foiled in every attempt to open it, I dissected down to it, cut through the contracted part, which was as hard as cartilage, and the wound is now very nearly healed. The patient makes water in a perfectly good stream. I yesterday saw a similar case, and intend to operate on it on Thursday.

In this obstinate form of stricture, there is not only contraction of the canal, but also a remarkable thickening of the part affected, which consequently is in general distinctly perceptible through the integuments, being felt like a ring of firm consistence, and flattened form. The bougie when introduced is firmly grasped, so as to be withdrawn with difficulty, and the patient, so far from experiencing relief afterwards, usually suffers an aggravation of his distress. It is difficult to account for these differences from the cases of ordinary occurrence, or to explain the origin of a disease so peculiar in its characters. I have not been able to trace any connexion between the effect in question and the cause giving rise to it, or to distinguish any specialty of constitution favouring its production. But that there may be some predisposition depending upon the temperament, or other circumstances of individual limitation, would appear from the hereditary and collateral connexion occasionally observed between patients thus affected. A gentleman who was lately under my care for a stricture of twenty-four years' standing, told me that both his father and grandfather had died of the disease. And some time ago, I divided the stricture of a patient who was one of five brothers, three of whom had died of the disease; a fourth, who is now well, had been under my care; and this, the fifth, had run an extraordinary gauntlet of treatment, of which it may be sufficient to mention a year or two passed under the care of Mr. Guthrie, who employed a succession of catheters, and afterwards caustic; a prolonged residence at Gräffenberg, under the water-cure; and a trial of Parisian homœopathy, which nearly proved fatal in a negative way, by disregarding an extravasation of urine that took place, all through the scrotum, and over the lower part of the abdomen, and but for the skilful care of M. Cloquet would doubtless have proved fatal. It is a fact of much practical importance that there is seldom, if ever, more than one contraction of the unyielding or resilient kind in the same urethra.

Having frequently had occasion to witness the distress resulting from this form of stricture, and to regret the insufficiency of any known means of remedy, I had great pleasure in communicating to the profession a safe, easy, and effectual method of overcoming the difficulty, which consisted in dividing the contracted part of the canal upon a grooved director passed through it. The speedy and complete relief thus afforded, even in cases of the most protracted and aggravated suffering, is one of the most gratifying services that can be rendered by the art of surgery. The favourable anticipation originally entertained of it has been more than realised; and any patient who continues to suffer from obstinate stricture, can no longer attribute his wretched state to the imperfection of surgery. In the present and following papers I propose to illustrate and confirm the statements which have hitherto been offered in favour of this treatment.

I have represented it as secure against the ordinary dangers which attend operations on the urinary organs—viz., hæmorrhage, inflammation, and infiltration of urine; and may now appeal to the evidence of forty-four cases which I have thus treated without encountering any of these effects, even in a single instance. It is quite true that through awkwardness, or defective acquaintance with the parts concerned, the artery of the bulb may be cut, and other errors of a serious nature be committed, so that I am not prepared to deny the allegation of this procedure being attended with danger in "inexperienced hands." But any man of ordinary skill, who chooses to follow the directions which I have given for conducting the process, will find little difficulty in accomplishing it. And here I may remark that my commentators who speak of "long incisions" in the perinæum, and laying open the urethra to the extent of several inches, have no warrant for such statements in anything that I have said or written on the subject. I never open the urethra beyond the extent of an inch, and seldom beyond that of half, or two-thirds of an inch.

The bleeding at the time of the operation hardly ever exceeds one or two teaspoonfuls; but occasionally takes place some hours afterwards, to the amount of an ounce or two, being apparently proportioned to the hæmorrhagic disposition of the patient, and therefore to be deemed rather salutary than otherwise. If any circumstance should render it desirable to prevent the chance of this discharge, a piece of lint put into the wound at the time of its infliction will effectually do so.

As to the question of "impermeability," I simply maintain, that if the urine passes out, instruments may always, through care and perseverance, be got in beyond the contraction. It should be observed that the case here is quite different from that of a distended bladder requiring *immediate* relief. I have never maintained that in such circumstances the introduction of a catheter was always practicable; and although in the course of two-and-twenty years of hospital practice I have not happened to meet with a stricture that resisted this instrument, I neither profess security of being equally fortunate for the future, nor teach such confidence to others, especially if they are not to be daily practised in overcoming obstructions of the urethra. In my Principles of Surgery, it is said—"If the surgeon possesses the requisite tact for introducing instruments into the bladder through the urethra, and has the treatment of the case from its commencement, he will very rarely, perhaps never, be under the necessity of resorting to this puncture. But should he not be able to draw off the water by the catheter, either from his own want of dexterity, or from the existence of obstacles arising from mismanagement or previous organic alteration of the passage, as stricture or enlargement of the prostate, complicated with a lacerated, softened, swelled, and bleeding state of the lining membrane, caused by forcible attempts to pass an instrument, there can be no hesitation in having recourse to the operation. Puncture of the bladder, however performed, is always attended with more or less danger of urinous infiltration; but a doubtful remedy is better than none; and there are few states of disease more hope-

Dublin Medical Press

less than complete retention of urine, permitted to follow its own course." (p. 359).

But if sufficient time and opportunity be afforded, I firmly believe that every stricture may be rendered permeable. I feel deeply impressed with the importance of this principle, and with the view of establishing it—not, certainly, to obtain an advantage over my professional brethren—I have again and again offered to undertake the treatment of any stricture, however impermeable it might be deemed, that was sent to the hospital. All those hitherto received have been afforded complete relief, either by simple dilatation, or by incision after being rendered permeable; and I venture to hope that the results in future will be no less satisfactory.

With regard to the permanence of effect obtained through incision, in my earlier communications I could only express the expectations which seemed to have a reasonable foundation; but now, with the advantage of seven years experience, I am able to speak more decidedly on the subject. It is well known that cuts, lacerations, and even slight bruises of the urethra from external violence, are almost sure to occasion stricture of the canal, unless a full-sized instrument be passed occasionally for a few weeks after the injury has been sustained; and I have, therefore, always considered attention to this circumstance essential for success. The first three cases of stricture at the bulb in which division was effected, after being treated in this way, seemed so completely divested of their contractile tendency that I expected it would never be necessary to use any precautionary measures by introducing bougies beyond the period just mentioned, immediately subsequent to the operation. In many patients this expectation has been fully realised, but in others it has been found necessary to introduce bougies for a longer time. How far these exceptions may depend upon some imperfection in the performance of the operation, the mode of healing in the wound, irritability of the system, or impropriety in the patient's mode of life, it is not very easy to determine at present, although more definite ideas may probably be acquired from more extended observation. In the meanwhile I feel warranted to state, that if the stricture be thoroughly divided, and a full-sized bougie be passed occasionally for a month or six weeks afterwards, the patient will certainly obtain complete relief from all the distress which attends the obstinate form of the disease, and require at most merely the precautionary treatment which is found sufficient to prevent the ordinary form of stricture from being troublesome. In illustration of what has been stated, I will now commence a relation of facts, which shall be continued so long as such information seems to be required by the profession.

Immediate Effects of the Operation.—As it has been alleged, and perhaps believed, though I should hope by few, that, in order to recommend the treatment of stricture by external incision, I have glossed over the unpleasant consequences of this procedure, and made it appear less formidable than the reality, I hope the following evidence will satisfy every reader who entertains any doubt upon this part of the subject, that I have not underrated the effects of the operation. To show that I do not resort to division of strictures unnecessarily, as had also been insinuated, or until dilatation is found altogether unavailing for the patient's relief, I stated in the last number of this journal the leading particulars of all the cases which had been subjected by me to operation in the Royal Infirmary, during the winter session just concluded. They amount to seven in number, and, together with an eighth which has since occurred, were treated publicly in the hospital. All the operations were performed in the theatre before the most numerous class of surgical clinical students in her Majesty's dominions, who can testify that the object in view was always attained without delay or difficulty, and that in no instance did the bleeding exceed in amount a teaspoonful. In regard to the hæmorrhage, or rather the absence of hæmorrhage, subsequently to the operation, as I cannot speak from my own personal observation, it may be satisfactory to give the house-surgeon's account of what fell within his observation, which was constantly fixed on the patients :—

Royal Infirmary, Edinburgh, May 16, 1851.

My dear Sir,—During the last seven months there have been eight cases of stricture of the urethra in the hospital, in which you have divided the stricture by external incision upon a grooved staff, previously passed through it. Every one of these eight patients I saw repeatedly in the course of the afternoon and evening after the operation, and I always took especial care to ascertain whether or not there was any bleeding from the wound. In every case the amount of hæmorrhage after the operation was very trifling—certainly never to such an extent as to make me think it at all necessary to use means for arresting it. In two or three of the cases there was no bleeding, or at all events not more than a single teaspoonful of blood; while the average amount of blood lost after the operation by all the eight patients was, I can confidently state, not more than *one fluid ounce* in each case.—I remain, my dear sir, your obedient servant,

Charles Murchison, Surgeon,
Resident Clerk, Clinical Surgical Wards.

James Syme, Esq., Professor of Clinical Surgery.

The gentlemen attending the hospital, who had daily opportunity of watching the progress of these cases, will not, I dare say, have forgotten the smiling aspect, grateful expression, and confident tone, with which my questions were answered. "How do you feel to-day?" "Quite well." "Have you any pain or uneasiness?" "None whatever." All these patients obtained complete relief, which will, I fully expect, prove permanent; but as sufficient length of time has not yet elapsed to test the permanency of their recovery, I produce them at present merely as evidence in regard to the immediate effects of the operation.

Non-existence of "Impermeability."—In December, 1849, I was applied to by a gentleman, who had come over from Ireland, in that state of extreme distress and suffering which results from stricture when the water can neither be discharged nor retained. He was aged 30, during twelve years of which he had been afflicted with the disease, and been under the care of many practitioners, not one of whom had ever succeeded in passing an instrument through the stricture, which lay between the scrotum and bulb. In a note of his case the patient gave me, he says:—"I was under Liston's care for nearly two months, and after his trying every other day to pass an instrument, I got tired of the expense, as well as the pain I suffered, and discontinued my visits to him. At—— [a large provincial town in England], I was attended for three weeks by one of the first doctors there, and nothing could be done for me by him. Also in America, many doctors have tried to pass the bougie, but always without success, and army doctors [the patient was a military officer] without end."

In a letter from this gentleman, dated the 10th of March, 1851—that is, more than a year after I had divided the stricture upon a director passed through it—the following account is given of his condition :—"On my return, last Saturday, from England, I found your kind note, inquiring after my health. In answer, I am delighted to be able to tell you, that I have never felt the slightest return of my old malady. I sometimes pass No. 7, but it is only to satisfy myself, as I think now it is of no use doing so. My health [which had been much broken when he was under my care] also never was so good; and I can undergo more fatigue, which I do, than I ever could in my whole life, and for this I may thank you, which I heartily do."

Permanence of Effect produced by the Division of Strictures.—The patient whose case is the fourth related in my treatise on stricture, lately presented himself at the hospital, and afforded an opportunity of ascertaining the result of his treatment. As the case is not long, it may be here reprinted :—"J. T., aged 36, was admitted into the Royal Infirmary, on the 29th of November, 1847, suffering very severely from stricture of the urethra. He stated that, about three years before, he had lain intoxicated in the street, during the whole of a winter night,—in the morning finding himself (to use his own expression)

"frozen to the ground;" and immediately afterwards had begun to suffer from the symptoms of stricture. In the course of the preceding winter, he had been eleven weeks in the hospital under treatment by dilatation, with considerable but only temporary relief, as the symptoms returned very soon after his dismissal. In these circumstances, it appeared necessary to divide the stricture, which was extremely tight, and seated at the bulb. I performed the operation on the 2nd of December; the catheter was removed on the 4th; and the patient was dismissed, with complete relief from his complaint, on the 3rd of January."

For three years afterwards he had continued (to use his own expression) as well as any man in the world, but then caught a gonorrhœa, and suffered from a partial return of the symptoms for which he had applied to the Perth Infirmary, and had bougies passed, with the effect of relieving him. Five months having subsequently elapsed, I found the urethra perfectly free, and introduced instruments of the full size without any difficulty.—*Edin. Monthly Jour.*

(To be continued.)

ON THE TREATMENT OF OBESITY.

By Dr. T. K. Chambers.

The subject of corpulence has not met with such consideration as it deserves; we, therefore, have great satisfaction in being able to lay before our readers an extract from a series of papers in which the light of modern science has been most admirably concentrated upon it. Obesity, though too often the subject only of witticism, is in many cases a real evil; and the practitioner will therefore gladly avail himself of any rational mode of obviating its inconvenience. In regard to treatment, Dr. Chambers observes:—

That form of disease which commences at birth, and goes on increasing during infancy and childhood, is, I believe, so invariably fatal before the age of puberty, that I do not think we have reason for hoping that it is in any way amenable to medicine. At all events, I have not been able to discover any one whose experience has led him to pronounce it curable. It is a form of monstrosity; and as the subjects of it commonly display some other bodily malformation, and a deficiency of intellect, their death is a relief from a miserable prospect.

When it begins in childhood, or about the time of puberty, we must not be deterred by the circumstance of its being hereditary from attempting to remedy the inconvenience arising from it. We cannot truly reduce our patients entirely to the average size and weight, but we may enable them to pass life in comfort and usefulness.

The later the disease commences, the more controllable it is by management, until the middle period of life is passed, and then old age impedes in some degree the benefit which we may confer, not by rendering our measures inert, but by preventing our employing them quite so actively as we should have done earlier.

The first thing indicated, in all cases, is to cut off, as far as possible, the supply of material. Fat, oil, butter, should be rigorously interdicted in the diet table. But all eatables contain some portion of oleaginous matter, and especially those most convenient to advise the use of for a lengthened period; and almost all are capable of a transformation into fat, when a small quantity of this substance is previously present. It is desirable, therefore, that the mass of food should lie in the stomach as short a time as possible, in order that at least a fatty fermentation may not be set up in it. Very light meals should be taken at times most favourable to rapid digestion, and should consist of substances easy of solution and assimilation. To this end, the time of the meals should be fixed for an early hour in the day, before exertion has rendered the powers of the entrails languid and weak. Breakfast should consist of dry toast, or what is still better, sea-biscuit; and if much active exercise is intended, a small piece of lean meat. Dinner at one, on meat with the fat cut off, stale bread or biscuit, and some plain-boiled maccaroni, or biscuit pudding, by way of second course.

Liquids should be taken, not at the meal, but half an hour after, so as not to impede the action of the gastric juice upon the mass. Here should end the solid feeding for the day; no second dinner or supper should follow, nor, indeed, any more meals be taken sitting down. A piece of biscuit and a glass of water can be taken standing up, if faintness is experienced; a cup of gruel or roast apple before going to bed.

This is not a scale of diet by any means unattainable. A butcher and retired pugilist has adopted it for some years with the greatest comfort to himself. He is able, upon it, to work in the most violent manner in a small garden which he cultivates for himself in the suburbs. He has reduced himself from twenty to seventeen stone; whereas his brother, who has not the same strength of mind, has increased to twenty-three stone in weight. Persons of more refined education ought, and often do, practise the same self-imposed restraint more easily. J. R—— has reduced himself from twenty-two to eighteen stone, and sometimes brings himself down to seventeen, but finds that he derives no particular advantage from being of the lower weight.

The smallest amount of nutriment consistent with the health of the individual can be found by experiment only; but we need not fear that ten ounces of solid food a day is too little, for the last-mentioned gentleman confined himself for a long period to that quantity, and found his mental and bodily powers always equal to the strain which the pursuit of a laborious profession in London demands. It may be remarked, by the way, that it is often advisable to add a small allowance of malt liquor at dinner, as otherwise the craving of the appetite is less easily appeased. The beers to be avoided are of course the thick, sweet kinds, but that which is thoroughly fermented, at a low temperature, in the Bavarian way, seems to contain very little injurious matter.

I do not know that any advice concerning sleep is peculiarly applicable to obese persons, beyond what we should recommend to all classes of men. A draught of morning dew, "nocturni roris auram ante solis ortum bibendam," which Aurelian prescribes for the corpulent, is equally beneficial to every one. They are usually uneasy sleepers, and though lethargic, by no means averse to early rising.

In cases where the fat is largely accumulated in the omentum, it is very convenient for the patient to wear a band round the abdomen, which may tightened gradually. The support thus given to the abdominal muscles relieves the dragging sensation in the loins, which many persons, whose viscera are heavy in proportion to their strength, experience. It enables exercise to be taken with more facility, and appears also, by pressure, to afford some assistance to the absorption of fat.

The above remarks will apply equally to all forms of obesity; the abstinence recommended can be borne even by the aged, and only comfort be experienced.

As respects exercise, however, a distinction requires to be made. The young and vigorous, whose obesity does not prevent the use of their legs, cannot employ them more usefully than in walking as long as they are able. The greater number of hours per day that can be devoted to this exercise, the quicker will be the diminution of bulk. But as riding, by the gentle shaking of the abdomen, excites the secretions of the digestive organs more, it should, where practicable, be employed in addition. Where freedom of motion has once been gained, rowing, shooting, any or all of the forms of British gymnastics, should be adopted as regular habits.

But in the asthenic form of the disease, especially in elderly people, this is scarcely practicable. The defect in muscular power prevents the use of the limbs in walking for a long time enough to be advantageous. But where riding can be managed, it should on no account be omitted, and the suspensory belt before mentioned is often a valuable auxiliary to the employment of this exercise.

The ancients were much more in the habit than we are of using various forms of friction to the skin in treating

chronic complaints; and we find in Aurelian a recommendation to the corpulent to employ dry rubbing, either with cloths alone, or with the addition of various powders. Modern habits of cleanliness supersede, in some degree, these remedies. But the skin is not unfrequently greasy from a thick sebaceous secretion, and the circulation through it languid in asthenic obesity, and in these cases horsehair gloves may be used with great advantage. Dr. Flemyng strongly advises friction to be employed to the trunk of the body as promoting absorption and invigorating the surface. The Greek additions of cold bathing or sponging, especially with sea-water, the vapour or hot-air bath, followed by rubbing with salt or with sand, and many other modifications of the same principle enumerated by Aurelian, will naturally suggest themselves to every intelligent patient. The same author very sensibly advises these remedial measures to be employed fasting, and no food to be taken for some time afterwards, and modern habits render before breakfast a convenient time. To these rules of management, medicines, strictly so called, must be viewed as secondary and auxiliary. Unless these laws are obeyed, pharmacopœias are useless.

Purgatives I have generally found not needed in the plethoric form; the bowels usually act once or twice in the day. But in the asthenic obesity *of old people*, where the abdominal walls are weakened by long pressure of an unnatural weight, it is necessary to employ them.

But there is one class of medicines so universally applicable to *all* cases of obesity, that I think a trial of them should never be omitted. The chemical affinity of alkalies for fat, point them out as appropriate alteratives in this complaint, and experience proves that they are suitable to the state of the digestive organs. The most eligible one is liquor potassæ, and it may be administered in much larger quantities than any other. If given in milk-and-water, we may safely commence with half a drachm, and raise the dose to a drachm and a drachm and a half three times a day. The milk covers the taste of the potash better than any other vehicle. It has truly the advantage of saponifying a portion of the remedy, but there is no evidence to prove that its efficacy is thereby endangered; indeed soap itself has been strongly recommended. A physician, whose case is recorded by Dr. Flemyng, reduced himself, by alicant soap alone, two stones in weight.

I have often given the above-mentioned doses of liquor potassæ (even to children in cases of scrofula and consumption) without any harm arising from its use, when taken, as desired, in milk. The fear of alkaline medicines has probably arisen from the injury observed by Huxham to follow the use of Mrs. Stephen's saponaceous mixture, at one time so popular, and therefore often misapplied. The injury appears to have originated from their having been employed in improper cases, such as debilitated gouty subjects, chronic stone in the bladder, and the like, to which, of course, much harm would be done.

A poor woman who sold eggs in Chelsea, was becoming quite unable to gain her livelihood by her ordinary occupation. I have not kept a note of her weight and height, and therefore she is not mentioned in the table of cases, but she was extremely obese, and the cause of a variety of symptoms she complained of seemed traceable entirely to the accumulation of fat. By taking liquor potassæ only, without change of diet, she was reduced so far as to carry on her trade with comfort.

Another case was communicated to me the other day, of a gentleman who weighed 19 stone 7 lbs. By regimen, exercise, and liquor potassæ, he was reduced two stone and a half in six weeks.

I have mentioned bleeding, and perhaps that may cause some surprise, after the observations which have been made on the state of the circulation in fat people. But where distinct signs of plethora are present—such as pain over the eyebrows, beating of the temples, restless sleep by night, lethargy by day, with full lips and an elastic skin—it is capable of being employed with safety; and where it is employed, the advantage derived at the commencement of a course of treatment is very great, for it gives all the other remedies a fair start; and by affording immediate relief to many symptoms, gives the patient a favourable opinion of the plan he has undertaken.

On the other hand, it is scarcely necessary to say, that much risk attends the loss of blood; for if the heart has become atrophied and weak, it will not stand the shock. Venesection may cause either sudden death, from failure of the heart's action, or effusion of blood in the brain, from disturbance of the circulation.

Bitter tonics are often of great advantage in enabling the stomach to digest more easily and rapidly, and therefore to be contented with a smaller quantity of really nourishing food. The increase of appetite which they cause does no harm; for when patients are getting better, they are usually more obedient to their medical man, and can be taught to control it. Gratitude for the benefit they have received makes them glad to follow advice, however hard.

Some medicines must now be mentioned, which have been recommended for the cure of obesity, but which analogy and experience do not approve.

Vinegar has been employed by those who are foolish enough to practise upon themselves; but as it produces thinness only by injuring the digestive organs, the benefit is not worth the price paid for it, and no medical man would ever advise the use of such a remedy.

Iodine has been spoken of as likely to do good, from the power it exhibits of stimulating the absorbents in cases of scrofula and tumours. But its moderate use certainly does not cause the disappearance of healthy fat. Indeed it has been noticed by Lugol, and is matter of daily observation at our metropolitan hospitals, that patients frequently acquire a considerable degree of *embonpoint* during the time they are taking iodine. The cases of tumours and of fat are very distinct. As Dr. Pereira remarks: "The enlargements which these agents (mercury and iodine) remove, are not mere hypertrophies; their structure is morbid, and they must in consequence have been induced by a change in the quality of the vital activity; in other words, by morbid action. Medicines, therefore, which remove these abnormal conditions, can only do so by restoring healthy action." But the action which causes the deposition of fat in the adipose tissue is, though excessive, of a healthy nature, and harm, rather than benefit, is to be expected from the medicine under discussion; that harm which always accrues from a valuable remedy wrongly employed.—*Lancet.*

ILIUM RUPTURED BY VIOLENCE—PERITONITIS.

Mr. Pemberton has communicated the following case to the Birmingham Pathological Society:—Joshua Woodhouse, aged 75, a gun-stock maker, presented himself at the hospital on the evening of May 29th, 1849. He appeared greatly prostrated in condition, and was suffering acute pain, but could give little account of himself. On examination I found him to have an inguinal rupture upon the left side, which I reduced with some degree of difficulty, the application of the taxis giving him considerable pain. I learned upon inquiry, that upon the 28th he had become entangled in the machinery of a large grindstone, and had been carried along the revolving wheel, his abdomen at its lower part receiving a severe blow. He wandered about after the accident, holding his hands across his belly, and complained severely of pain. He did not go to work on the next day, but in the evening came to the hospital. There was no abdominal tenderness on pressure; and no external evidence of injury.

May 30th. Respiration laboured; general appearance more depressed than on the previous evening; at two p.m. he died.

Sectio-cadaveris, twenty-four hours after Death.—Thorax: The contents were natural. *Abdomen:* The parietal and reflexed peritoneum was covered everywhere with flakes of lymph; large collections of pus existed in the iliac fossæ and dependent portions of the cavity; the in-

testines on their convex surfaces were covered with lymph, and adhered by bands of the same material. Globules of castor-oil were visible, floating on the purulent fluid. On removing the intestines, the portion that had escaped from the cavity into the inguinal canal, was found to be a portion of ilium near its termination in the cæcum. It presented no morbid change beyond some slight adhesions upon the inner surface. On tracing the ilium further upwards, a rupture in its coats was found to exist near its commencement in the jejunum. This rupture was situated about half an inch from the mesentery, and was about half an inch in its longest diameter, which was placed in the short axis of the intestine. Looking at the edges of the opening from the inner surface, they are seen to be smooth and perfectly even, whilst on the outer aspect they are broken and uneven. No inflammation is observable as existing especially in the vicinity of the opening. The remainder of the intestines natural.—*Prov. Jr.*

REVIEWS AND NOTICES OF BOOKS.

ON ANIMAL CHEMISTRY IN ITS APPLICATION TO STOMACH AND RENAL DISEASES. By H. Bence Jones, M.D., F.R.S., of St. George's Hospital. 8vo. pp. 139. London. 1851.

This work was before us for review when Dr. Bird's, noticed in our last number, was under consideration, and was alluded to in consequence, although not named. We now have to direct the particular attention of our readers to its contents, and especially to the greater portion, treating of renal physiology and pathology. We cannot better make known to our readers the nature and object of this work than by copying the table of contents. We consider it a valuable contribution to the department of pathology to which it refers: a department worthy of the special attention of all practitioners. The investigation of renal diseases has thrown more light upon the study of physiology and pathology than the investigation of the diseases of any other organ; and for this plain reason, the products of secretion and disturbance of function of the kidney are more easily ascertained than those of other parts of the animal economy:—

Lecture I., on Food.—Comparison of animal and vegetable food; in all food, four classes of constituents, water, ashes, non-nitrogenous and nitrogenous organic matter; the proportions of the constituents vary; amount of nitrogenous substance determines the value of the food; animals have no power of forming the different classes; each class must be present in food; chemical transubstantiation not proved; the relation of food to air and exercise; respiration, gaseous food; animals serve for the support of vegetables.

Lecture II., on Digestion.—Bread and water the type of the food of man; digestion divided into solution and absorption; requisites for solution; quantity to be digested as important as quality; nature of the gastric juice; contains water, acids, salts, and organic substances; variations in the acidity of the stomach; action of gastric juice on nitrogenized food; on starch and on sugar; on fat and oil; the action of the gastric juice is a chemical action.

Lecture III., on the Blood.—Assimilation of food to blood, sanguification; unceasing changes in the blood; mode of analysis; analytical formula; variation of constituents of the blood in disease; in gout, urate of soda in the blood; history of two cases of gout; hippuric and oxalic acids in blood.

Lecture IV., on Calculi.—Natural analyses of the urine; causes of the formation of calculi; calculi destroyed by heat, uric acid; calculi not destroyed by heat, oxalate of lime; method of distinguishing phosphatic calculi; silica calculus; calculi whilst moist support infusoria; table for examining urinary calculi.

Lecture V., on the Quantity and Acidity of the Urine.—Causes of the variation of the quantity; variation of the specific gravity; effect of diet and exercise; solid residue bears no proportion to the specific gravity; variation of the acidity of urine and stomach; method of determining the variation of alkalescence; effect of animal and vegetable food on acidity; of sulphuric and tartaric acids and tartrate of potash; nature of the acid in the urine; reaction of test paper insufficient.

Lecture VI., on Uric or Lithic Acid.—State in which the uric acid exists in the urine; variations of the uric acid in health; mode of determining amount of uric acid; influence of vegetable and animal food on the uric acid; comparison of these two kinds of food; formation of a deposit no proof of the presence of an excess of uric acid; precipitation depends on the acidity of the urine; other causes of the deposit of urates; free uric acid caused by acidity alone; of the treatment of uric deposits when crystalline; of the treatment of uric deposits when not crystalline.

Lecture VII., on Oxalate of Lime and Sulphates.—Oxalate of lime of no serious importance; relate to uric acid; soluble in urine; chemical analysis of octahedral crystals; other forms of oxalate of lime; when it may be suspected to be present; how proved to exist; treatment of oxalate of lime; on the sulphuric diathesis, or excess of sulphates in the urine; mode of determining sulphuric acid; effect of animal and vegetable food on the sulphates; effect of exercise and sulphuric acid; effect of sulphur; mere inspection tells nothing regarding the sulphates.

Lecture VIII., on the Alkaline and Earthy Phosphates.—Compounds of oxygen and phosphorus; phosphates of soda; most important tribasic phosphates; alkaline phosphates more important than the earthy phosphates; method of determining the variations of the alkaline and earthy phosphates; effect of vegetable and animal food on their amount; effect of chloride of calcium and sulphate of magnesia; general conclusions; phosphatic diathesis only alkalescence of the urine; excess of alkaline totally distinct from excess of earthy phosphates; variation of the phosphates in disease; treatment.

Lecture IX., on Alkalescence of the Urine from fixed and Volatile Alkali.—Effect of the mucus on decomposition; relation of urea to carbonate of ammonia; effect of ammoniacal urine on pus; alkalescence not always caused by carbonate of ammonia; mode of distinguishing alkalescence from fixed alkali, from ammoniacal urine; precipitation of phosphates by heating alkaline urine; comparison of alkalescence from volatile and fixed alkali; on urea, chemical properties; method of determining the quantity of urea; relation of the amount of urea to the specific gravity; excess and deficiency of urea; treatment of alkalescence.

Lecture X., on Albuminous Urine.—Healthy urine contains no albumen; fallacies of tests for albumen; mineral acid hinders coagulation by heat; what the albumen indicates; the importance of the substances that accompany the albumen; for instance, fibrin-blood and pus globules; the treatment must be determined thereby; a new albuminous substance not precipitable by heat and acid; chylous urine; vegetation in albuminous urine, penicilium glaucum; microscopical appearances in Bright's disease.

Lecture XI., on Diabetes and Diuresis.—Sugar formed in health; reduction of copper test for sugar; reduction of silver, and potash test; crystalline appearance on evaporation; frequency of the disease; caused by the arrest of healthy changes; history of diabetes insipidus; Bourchardat, his statements; Dr. Simon, his case; quite distinct from diuresis; treatment of diabetes; cod-liver oil in this disease, case; sugar in small quantities probably very frequent; relation of diabetes to excessive acidity.

Lecture XII., on the Relation of the Urine to the Food and Animal System. General Method for its Examination.—Unhealthy states of the urine by no means always depend on disease of the kidney; the kidneys separate from the blood useless and hurtful substances; effect of too much food and too little exercise; relation of the urine to the respiration; on the effect of the oxygen inspired; relation of the colour of the urine to the bile; senna as well as rhubarb colours the urine; effect of oxygen on the salts in the urine; very many diseases have a peculiar effect on the urine; importance of the examination of the urine; mode of proceeding, after quantity, colour, and acidity; then specific gravity, and microscopic appearance; example of the knowledge that may be obtained; conclusion.

A GOOD HINT TO DISPENSARY SURGEONS.

At the annual meeting of the governors of the Whitehouse Dispensary, held on the 31st of May, it was unanimously resolved—"That, as the Medical Charities' Bill is still before parliament, it is, in the opinion of this meeting, necessary that the subscribers be respectfully requested to continue their subscriptions the same as last year."

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, JUNE 25, 1851.

POISONOUS PROPERTIES OF RICE.

Be not startled, gentle reader, at this alarming heading to our hebdomadal chapter on passing medical events. It is not an announcement of a discovery touching the direct and rapid effect of rice as a poison, it is only a sober and official notification that, as an article of diet, it is not to be relied on for the support of life and health. In a letter addressed to the Guardians of the South Dublin Union by the Secretary of the Poor-law Commissioners, it is stated that "their Inspector, Mr. Phelan," finds that the children get rice three days in the week, which he does not consider "judicious," it not being "an equivalent for bread;" and therefore being the cause of their delicate health. This is a new view in dietetics; but we must, on such authority, come to the conclusion that it is the correct one. The Commissioners do not entertain their notions touching matters medical lightly; they are always well advised, and in the sequel they will, doubtless, enlarge the boundaries of our art. Last year they added the great pathological fact of the "cold nose" to our stock, and established the importance of that great diagnostic symptom of poorhouse ophthalmia. This year they announce the instructive fact, that the infant children of Irish paupers are not sickly because they and their mothers have been subjected to privations, but because they eat rice three days in the week. Fortified, as the Commissioners are, by the advice and opinions of the most learned, eminent, and trustworthy members of the medical profession, we are bound to accept their decisions with confidence and gratitude, and therefore have we resolved from henceforth to advocate abstinence from rice as a hygienic measure of salutary precaution. The following, however, will explain more fully the true state of the case:—

SOUTH DUBLIN UNION.

At the usual weekly meeting of the guardians of this union, on June 12, the following was read:—

Poor-law Commission Office, Dublin,
5th June, 1851.

Sir,—I am directed by the Commissioners for Administering the Laws for Relief of the Poor in Ireland, to state, for the information of the Board of Guardians of the South Dublin Union, that they have received a report from their inspector, Mr. Phelan, relative to his recent inspection of the workhouse of South Dublin Union. Mr. Phelan adverts to the delicate state of health of the infants, and states that they get rice instead of bread on three days in the week. This arrangement in regard to dietary he does not consider judicious, and recommends that it be discontinued as a general practice; but, in addition to the ordinary dietary, bread and milk and a small portion of boiled rice be given to any infant for whom the medical officers consider it necessary. Mr. Phelan also states that rice is not an equivalent for bread for infants, and he is of opinion that the delicate health of those inmates may be partly attributable to the diet.—By order of the Commissioners, W. Stanley, Sec.

June 12, 1851.

The medical officers have had under consideration the communication from the Poor-law Commissioners to the Board of Guardians of the South Dublin Union, relative to the health and the dietary of the infants, and in compliance with the request of the board they proceed to state their opinion upon both these topics.

The delicate state of health of the infant inmates of the workhouse has long been the subject of anxious and painful consideration to the medical officers (as many of their reports to the board attest), and they are of opinion that it is attributable to many causes, some of which are unfortunately not within the control of the Poor-law Commissioners, the guardians, nor the medical officers; whilst against others, strenuous exertions have been made by the board from time to time, at the suggestion of their medical officers. A certain number of the infants are orphans, a class amongst which the mortality is necessarily excessive; for even in private life, and under the most favourable circumstances, artificial feeding seldom succeeds as a substitute for breast milk, and the statistics of all foundling hospitals show that in such establishments every plan hitherto devised has been a failure—the want of natural care and tenderness, and the loss of its natural nourishment, being generally very fatal to the young infant. Another very large section of the infants are illegitimate, many of them born in a state of disease, and the majority of them belonging to abandoned women, ignorant, careless, and often even designedly neglectful of their children. Many of these women also have had their health broken down by previous disease, and consequently make but indifferent nurses. A third class of the infants belong to parents driven to the workhouse by destitution, and reduced in health by privation and suffering, both mentally and bodily. Such women, however well disposed, are precluded by their own delicacy from affording healthy nutriment to their infants; but even under the most favourable circumstances of previous good health, mental depression, consequent upon altered position in life, is apt to exercise a most injurious influence on the workhouse nurse. When, from any of these causes, the mother's health appears to be impaired, the infant's must be delicate: a sickly wet nurse can hardly rear an infant healthy. Of the weaned infants, a large portion come into the workhouse in a delicate state of health, and many of them even labour under incurable organic disease upon their admission.

In addition to the foregoing, there are other fruitful sources of disease amongst workhouse infants. Epidemics spread rapidly amongst them. Beyond all other classes they require pure air, and the strictest attention to their cleanliness and comfort: the scrofula cachexia being the certain result of over-crowding and of defective ventilation. To counteract so many causes of disease would be impossible, but much has been done to obviate such as are remediable.

A large hospital ward at a distant part of the building had been set apart for the purpose of preventing to the utmost the spread of contagious diseases, by separating the sick from the healthy infants. The necessary dormitories are spacious and airy, and the day rooms are the best which the workhouse affords. A special officer superintends the feeding and the washing of the infants, and the distribution of their medicines; it is also her duty to compel the nurses with their infants to take sufficient air and exercise out of doors daily, and for this purpose the garden, by a board order, has been made available.

As regards the nursery dietary, the following has been the general allowance to the infants for several years past:—

Infants at the breast, four days in the week, 8 ounces of bread daily and 1 pint of milk daily. Three days in the week, 2½ ounces of rice daily, and 1 pint of milk daily.

Weaned infants, four days in the week, 12 ounces of bread daily, and 1 pint of milk daily. Three days in the week, 2½ ounces of rice daily, 1 pint of milk daily, and 4 ounces of bread daily.

In addition to these regular diets, the medical officer, at his discretion, is in the constant habit of ordering milk, sago, arrow root, beef tea, wine, whey, and even occasionally chicken broth, when necessary, and always of substituting bread for milk in cases which seem to require it.

The use of rice, as a particular substitute for bread in the nursery dietary, was originally introduced many years ago at the suggestion of the medical officers, and been continued by them to the present day with a view of varying the infants' food—a principle of acknowledged utility in the construction of dietaries.

In consequence of the great tendency to bowel irritations amongst the infants, they found it impossible to select any better article as a substitute for bread, seeing also that so large a section of the human family subsist almost exclusively upon it, and reasoning besides upon the many facts adverted to in the early part of this report, they cannot subscribe to the opinion that the delicate state of health of these inmates may be partly attributable to this diet.

Bantering apart, does not this passage of poorhouse

hygiene prove two things: first, that this department cannot be effectively conducted without medical superintendence; and secondly, that such superintendence should be of the most perfect description. The Commissioners have now been for some years fumbling, stumbling, and blundering in the pursuit of such a provision, yet afraid to call for it; because the admission of a necessity for such aid involves the admission of a necessity for medical interference in the poor-law administration. They surreptitiously, and without legal warrant, appoint a medical inspector; but aware of the slender authority given to them to appoint such an officer, they metamorphose an apothecary they happen to find amongst their staff of inspectors into such an officer, and here are the fruits of it. If this department of the public service had the assistance of educated, well informed men, could we have the judicious arrangements of the surgeons of the South Dublin Union, to secure the variety of food so essential to the health of the children, questioned; or could the absurd suggestions for the treatment of the ophthalmia when prevalent have been foisted on the surgeons of other unions last year by a metropolitan recipient of the offals of official patronage? If we wanted a fact in addition to prove the necessity for a medical superintendence as part of our poor-law system, this before us supplies it, and comes opportunely to promote the enactment of the proposed Medical Charities' Bill.

MEDICAL CHARITIES' BILL.

We hope to have it in our power to report some satisfactory proceedings in the House of Commons respecting this measure in our next publication: it is down for consideration early this week, with a determination to bring the discussion of its details to issue. While alluding to the subject, we have to state that a pamphlet on the Medical Charities has been transmitted to us. Its author indulges in the comfort and comparative safety of an *incognito* character, assuming the comprehensive *nomme de guerre* of Medicus. Without troubling our heads to ascertain who the writer may be, we are content to discover who he is not. He evidently is not that victim to the *cacoethes scribendi*, the vigilant Medical Inspector of the Poor-law Commission; for there is no laudatory allusion to the vast services of that exemplary functionary. Neither is he the illustrious Commissioner of Vital Statistics, the *pro re nata* colleague of the same inspector, for the pamphlet says not a word about the bazaars of Cairo, where the Egyptian ophthalmia may be so successfully studied; nor yet again of Dean Swift's skull, or the beauties of the Boyne. Again, inasmuch as it embodies no paraphrase of that admirable passage, "long may they flourish who have aught to give," it clearly has not emanated from the medical poet laureate of the viceregal court, and universal candidate for everything a-going. We believe we can also say that it comes not from any other party suspected of a design on the Charities' Bill Commissionership. In fact, the writer seems rather to belong to the amateur class, who cultivate such matters for their own sake, and hence its value; for more or less valuable it is as a convenient guide to those who recoil from ponderous blue books. It seems to be a fair digest of the laws affecting the medical charities, and a candid explanation of the results of their operation. The writer has evidently not been crammed for his work, but draws upon a stock accumulated during a protracted consideration of the subject. He also displays a practical acquaintance with details, proving the truth of the "*haud ignara mali*" on his title page. We commend the work to our readers, convinced that in no other eighty pages will they find so much information on the subject.

THE UNIVERSITY OF ST. ANDREW'S AND HOMŒOPATHY.

To the Editor of the Lancet.

Sir,—As I am led to infer by your leading article in this morning's *Lancet* that you charge the University of St. Andrew's with having conferred the degree of doctor of medicine on a homœopathic practitioner, I must beg you to publish the accompanying extracts from the answers given by the gentleman in question, as well as a copy of the note which I have addressed to him on the subject of your editorial remarks.—I am, sir, your obedient servant,

George E. Day, M.D., Professor of Medicine.
University of St. Andrew's, June 7, 1851.

1. Name the emetics included in the Pharmacopœia, and state the doses in which they should be prescribed.

Answer. Ipecacuanha, tartar-emetic, sulphate of zinc, and sulphate of copper. The doses are, of ipecacuanha, one scruple; of tartar-emetic, from one grain to two grains, acting better if in combination with ipecacuanha; of sulphate of zinc, from five grains to ten grains; and of sulphate of copper, from two to four or five grains.

2. Name the cases in which croton oil, aloes, jalap, gamboge, scammony, and elaterium, are specially applicable, and the form and dose in which *you* usually prescribe them.

Answer. Croton oil is administered in cases of very obstinate constipation, where other milder purgatives fail. It is used externally as a powerful means of counter-irritation.

Aloes is a useful purgative where there is inertia of, or accumulation of feculent matter in, the sigmoid flexure of the colon, or in the rectum, and in cases of atonic dyspepsia, chlorosis, &c.

Jalap is a useful purgative in a variety of diseases, and is useful in cases of worms, &c., in children.

Gamboge and scammony are allied purgatives, the former being rather more drastic than the latter.

The dose of croton oil is usually from the one-eighth to the one-fourth of a drop, according to the strength of the patient and the urgency of the symptoms. It is seldom given uncombined, and generally in the form of pills.

Aloes are given in pills, in doses of from five to ten grains—generally given in combination with scammony, calomel, or blue pill. The decoction of aloes is a useful form, the dose being from half an ounce to an ounce and a half.

Gamboge and scammony, mostly in pills. Dose, from three to five grains of the former, and about the same of the latter.

Elaterium is a powerful hydragogue cathartic, useful in various forms of dropsy, in carrying off a large amount of serum from the intestinal mucous membrane. Dose, from one-sixth to one-fourth of a grain.

3. Write a Latin prescription for an expectorant mixture suitable for a case of chronic bronchitis; also for a warm aperient draught.

Answer.

℞ Misturæ ammoniaci, uncias quinque.
Tincturæ scillæ, drachmas duas.
— opii compositæ, drachmas duas.
Misce. Fiat mistura. Capiat cochleare unum amplum bis vel ter in die.

℞ Decocti aloes compositi, drachmas sex.
Tincturæ rhœi compositæ, drachmam.
Misturæ camphoræ, drachmas quatuor.
Fiat haustus quamprimum sumendus.

4. Describe the treatment of iritis.

Answer. Mercury is the chief remedial agent, preceded by general or local abstraction of blood, if the strength of the patient will bear it. It should be given in small, frequently repeated doses—half a grain or a grain of calomel. In small doses, first, because the system is more rapidly brought under the action of mercury when the doses are small and frequently repeated; and second, because opium being contra-indicated, owing to its effect in producing contraction of the pupil, it ought to be given in doses that will not irritate the intestinal mucous membrane, producing diarrhœa, by which it would be carried out of the system, and not absorbed into it. In the strumous diathesis, the mercury should be given

with caution; the doses should be smaller; and the bichloried often acts better than the chloride, in such cases. In the gouty and rheumatic diathesis, colchicum may be combined with the mercurial; and iodide of potassium is advantageous in some forms of the disease.

Besides the local treatment by leeching, the external application of belladonna and the exclusion of light are most important means to prevent the closure and adhesion of the free margin of the iris.

Counter-irritation may be demanded, in addition to other treatment.

5. Describe the treatment of acute laryngitis.

Answer. The treatment consists in active antiphlogosis, bleeding, leeching, &c.; the exhibition of mercury (calomel, two grains, every two, three, or four hours); but this may be preceded, in most cases, by nauseating doses of tartar-emetic (one-sixth to one-fourth of a grain), every two, three, or four hours. Leeches should not be applied over the larynx, owing to the difficulty of using pressure to stop the bleeding. Cupping to the nape of the neck is often better than leeches.

6. Describe the treatment of enteritis.

Answer. Antiphlogistic treatment here must not be so rigorous as in many other inflammatory affections, as there is a tendency to prostration. Local abstraction of blood, fomentations and poultices; the exhibition of mucilaginous drinks with the cautious exhibition of calomel or hydrargyrum c. creta, in combination with opium or Dover's powder, include the principles of treatment. In this disease, the exhibition of opium alone, with other means tending to diaphoresis, will often be sufficient; and under this treatment, the action of the bowels will become restored without the use of purgatives, which, in this disease, are questionable in any of the ordinary forms.

7. Mention the treatment of the various forms of intestinal entozoa.

Answer. For the tape-worm; the best remedy for ejecting it is the oil of turpentine, given in doses of from three drachms to five drachms, with castor oil.

The lumbrici are expelled by many purgatives, which have the effect of producing mucous stools, as calomel and jalap, scammony, &c.

Ascarides may be got rid of by using, in addition to the above, enemata of infusion of quassia.

In all cases of worms, the tone of the digestive apparatus should be improved by tonics and alteratives.

Although the above extracts from Dr. Hale's written answers "specifying the mode of treatment he is in the habit of adopting, and the doses of the medicines which he prescribes" [see the note to our third Examination Paper], are, I think, sufficient to demonstrate that he cannot be a homœopath, I may add the additional evidence afforded by some portions of his oral examination in *materia medica*. Dr. Anderson was his examiner, but I was present, and noted down the questions and answers.

Dr. Hale stated that the doses of bichloride of mercury, when given as an alterative, varied from one-twelfth to one-sixteenth of a grain; that in croup (in the case of a child of three years of age), he would give one-sixth to one-fourth of a grain of tartar-emetic every four hours; and that in the pneumonia of adults he would give half a grain of the same medicine every three or four hours; that in prescribing hyoscyamus as a sedative, he gave eight or ten grains of the extract; and finally, that he used arsenious acid in certain forms of skin disease (the squamous forms), and in diseases of a periodic type, his dose being one-sixteenth of a grain, or from five to ten or fifteen minims of Fowler's solution.

GEORGE E. DAY.

Copy of Dr. Day's Note to Dr. Hale.

DEAR SIR,—There is an article in the *Lancet* of this week asserting that you have been, and still are, practising homœopathy. As no homœopathist, without utterly denying his creed, and being guilty of the grossest deception, could have replied as you did to the practical questions, I entertain a sanguine hope that you will meet this charge with a prompt and distinct denial. In order at once to check a report equally injurious to yourself and to the university from which you have received your degree, I forward by this post to the *Lancet* certain extracts from your answers to the practical questions, and a copy of the note I have now the honour of addressing you.—I am, dear sir, faithfully yours,

GEORGE E. DAY.

Dr. Robert Douglas Hale.

To the Editor of the Lancet.

SIR,—My name has been wantonly introduced in your journal; and I am represented as not having acted the part of an honest and conscientious man. My written answers to the questions put, at the May examination at St. Andrew's, to the candidates for the degree of M.D., will show, if they have been kept, that they were such as any honest and conscientious man might have written. For my professional attainments the university was my judge, not you; for the application of therapeutics I am responsible to my patients, to my own conscience, and to GOD, and not to you, or to any man, or to any body of men. My conduct and character will bear scrutiny, and I shall be glad to assist you in any investigation you may choose to institute in your tyrannous assumption of medical dictatorship, which, however, the liberal members of a liberal profession repudiate, as does your obedient servant,

ROBERT DOUGLAS HALE.

Norwich, June 10, 1851.

[We shall await with some interest the further proceedings of the University of St. Andrew's. The above letter scarcely requires notice, its evasions are so obvious.]—*Ed. Lancet.*

INSTRUMENT FOR CUPPING THE NECK OF THE UTERUS.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—I hope to be permitted through the medium of your valuable publication to call Dr. Mitchell's attention to the following facts relative to the instrument invented by me, to which he has referred in his observations to the Surgical Society of Ireland, as published in your journal of the 21st ultimo. I beg respectfully to inform that gentleman, that in the summer of 1849, I completed my instrument for cupping the uterus, and have in my possession a letter from Dr. Shekleton, Master of the Rotundo Lying-in Hospital, to whom I then submitted it, and who has tried it on several occasions; with other letters from several highly respectable medical men.

Dr. Mitchell will recollect having called on me recently to borrow one of my instruments, which I declined to lend, but offered to sell him; and I feel convinced if he had used my instrument with the glasses perfect, that he would readily admit that it is as useful for the purpose of making incisions as for puncturing, according to the wish of the operator, and would have discovered the advantage of its being superior to his instrument, inasmuch as mine can be worked with one hand, while his requires both hands to be used in operation.

I shall be happy to afford Dr. Mitchell, or any medical gentleman, an opportunity of inspecting the letters already alluded to, which settles the question of my being the original inventor of an instrument for cupping the uterus, and enabling the operator to take as much blood as may be required, without danger of the injurious consequences that Dr. Mitchell alludes to.—I am, sir, your very obedient servant,

ALEXANDER ROBERTSON.

Dublin, 22, Bachelors'-walk, June, 1851.

DISPENSING OF MEDICINE.

G. OLDHAM AND CO.,
PHARMACEUTICAL CHEMISTS, AND APOTHECARIES,
From BEWLEY and EVANS',
No. 107, GRAFTON-STREET, DUBLIN,
(Corner of Suffolk-street),

BEG to return their grateful acknowledgments to the Medical Profession for the support they have hitherto received, and which they will regard as a fresh motive for exertion. Abstaining altogether from visiting as Apothecaries, except for the application of Leeches, Cupping, and such operations as are performed under medical advice, they will continue to devote themselves exclusively to the duties devolving on the pure Pharmacien.

Having had much experience in Practical Pharmacy, and being resolved to spare neither trouble nor expense in order to have every article of superior quality, they hope by attention, "carefulness," punctuality, and moderation of charges, to commend themselves to the approbation of those who may entrust them with their commands.

☞ *G. O. and Co. invite attention to their present stock of Surgical Instruments, all of which are manufactured on the most modern and improved principles.*

ROYAL COLLEGE OF SURGEONS.

THE Professors of Anatomy will appoint a Demonstrator on MONDAY, July 14th. Candidates for the office should transmit their proofs of qualification, one week at least before the day of election, under cover to Mr. BOYLAN, the Registrar at the College.

UNIVERSITY AND KING'S COLLEGE, ABERDEEN.

THE Examination of Candidates for the Degree of M.D. will be commenced on Tuesday, 29th of July, and continued daily, till finished; immediately after which the graduation will take place. Those intending to become candidates are requested to forward the necessary documents, addressed to the Professor of Medicine, on or before the 12th of July.

REGULATIONS.

I.—Those who possess a diploma from any of the Royal Colleges of Physicians or Surgeons, or from the Apothecaries' Company, and who have been engaged for at least five years in the practice of Medicine, will be admitted to examination on producing their diploma, along with satisfactory evidence of good moral character, and of having studied the classics at a university or at an academy of acknowledged reputation.

II.—Those who commenced their medical studies in or before 1840, and who have not been in practice for five years, will be admitted to examination on producing, along with their diploma, evidence of sufficient preliminary education, of good moral character, and of having been engaged in the study of medicine for four years, during which they must have attended, in some recognized school of medicine, the following courses of lectures:—

SIX MONTHS' COURSES.

Anatomy	Two courses.
Chemistry	One course.
Materia Medica	One course.
Surgery	One course.
Institutes of Medicine and Physiology	One course.
Practice of Medicine	One course.
Midwifery	One course.

THREE MONTHS' COURSES.

Dissections	Two courses.
Practical Chemistry	One course.
Medical Jurisprudence	One course.
Clinical Surgery	One course.
Botany	One course.
Clinical Medicine	Two courses.

In addition to the above, the candidate must have attended for two years the wards of an hospital containing one hundred beds, and during three months a shop or dispensary for the compounding of medicines.

ANDREW FYFE, M.D.

King's College, Aberdeen, June, 1851.

N.B.—Attempts having lately been made to impose upon medical practitioners, by offers to procure for them diplomas from the University and King's College, Aberdeen, without undergoing examination, it is hereby intimated, that this University does not grant Degrees in Medicine, unless candidates submit to examination, conducted by the Medical Examiners in presence of the Senatus.

TERMS OF SUBSCRIPTION (PAYABLE IN ADVANCE).

Twelve months, ...	£1 5 0
Six months, ...	13 0
Three months, ...	6 6

SKETCH OF THE LIVES AND OPINIONS OF THE CHIEF ALCHEMICAL AND CHEMICAL PHYSICIANS OR IATRO-CHEMISTS.

By M. Donovan, Esq., M.R.I.A.

(Continued from vol. xxv., p. 405.)

Dubois, a surgeon, who had relinquished his profession and studied the occult sciences in the East, had become a monk, then a priest, and for a while a protestant, and finally betook himself to alchemy, made an exhibition in the presence of Louis XIII., his Queen, Richelieu, and others (1637). Musket balls being given him, he put them into a crucible with a little of the powder of projection, and placed the whole in a furnace under the observation of a person appointed to watch him at his own request. The heating being finished, the crucible was examined and found to contain a mass of gold. The astonished and delighted monarch could scarcely contain himself for joy: he heaped honours and emoluments on Dubois. The French finances being in a miserable state of exhaustion, the unconscionable Richelieu demanded of the unlucky alchemist to supply gold to the weekly amount of 600,000 livres. After a long practical equivocation, he was sent to the Bastile, and being put to the torture, he confessed his impostures, and was executed.

Alexander Sethon was imprisoned by the Elector of Saxony, tortured on the rack, and subjected to varied ill treatment for many months to induce him to discover his secret; but he endured all, and disclosed nothing, for a very obvious reason. Michael Sendivogius was imprisoned but escaped. It was no unusual device with princes to allure an alchemist under specious pretences into his power, and then to imprison him with a view of extorting from him an enormous ransom derived from his skill in transmutation.

Kircher attributes the practice of this art to the temptations of the devil, and founds his belief on a story imposed on him of an unsuccessful alchemist whom the devil urged on in the pursuit of this art, in order to reduce him to despair, and thus to take possession of his soul and body. The worthy father deduces the following moral, which, if applied in an allegorical sense, is excellent:—"Hanc historiam *veridicam* hic apponere volui, ut ex illa pateat quantopere dæmon hominibus auri cupidis studeat illudere, quot quantisque modis in suas casses, tum præstigiis, tum mille artium technis attrahere satagat."

The alchemistical notion received some countenance from those apparent transmutations which commonly occur in the arts; thus iron immersed in the impregnated water of copper mines dissolves away, and is replaced by copper retaining the original shape of the iron. Even so lately as 1751, this was believed in Ireland to be a true transmutation: an iron shovel left in the cupreous water of Crone-Bawn was found converted into a copper one. At the copper mine of Herun-Grundt, the miners used to show a cup of gilt copper which had been originally iron, and bore the inscription in German, "Copper I am, but iron was of old."

The frauds practised on the unwary by impostors professing to teach the art of transmutation and of preparing the universal medicine, had animated many princes and legislators with a desire to protect mankind from further deception. In this they failed. But during the seventeenth century a number of the most eminent philosophers of the age directed their energies against the alchemists with such resistless force, and exposed their fallacies and knavery with such effect, that the art of suddenly acquiring unlimited wealth and of living for ever fell into disrepute. To this result the efforts of Kepler, Gassendi, Kircher, Geoffroy, Conringius, and above all, the memorable labours of Boerhaave, mainly contributed. Gassendi, a learned astronomer, had been in early life an astrologer, but afterwards denounced it as an imposture and absurdity. Kircher had dabbled in alchemy, but at length became convinced that it is a delusion. Yet so lately as the middle of the eighteenth century such a man as Sir Torbern Bergmann declared that unless we reject history, we must admit these transmutations to be entitled to confidence.

Notwithstanding the overpowering attacks made by this

formidable phalanx, and the influence of it on the public mind, a few alchemists here and there continued to delude themselves or impose on others. Amongst the former was no less a person than Charles the Second, King of England, whose dissolute life caused him to be involved in frequent embarrassments. Such were the necessities of this improvident but good-natured monarch that, at one period of his reign, as Pepys declares (Strickland, viii., 386), he was almost without linen; he had only three cravats, very few stockings, and no credit at the linen-drapers. He fitted up a private laboratory, in which he made chemical experiments, but his chief object was an extemporaneous supply of gold; and to this end he laboured hard to fix mercury as a preliminary step. His grandfather James I. at one time, we are informed, had not money to supply himself with either bread or beer.

The last remarkable English alchemist on record was Dr. James Price, who, in 1784, made experiments in presence of several persons on transmutation of mercury into gold or silver, to produce each of which he used a different powder of projection, one red, the other white. His experiments were repeated many times before several scientific persons. His powders being expended, the interest which his transmutations excited induced the spectators to urge him to prepare more of them in presence of scientific persons; but this he refused, and in some time after the unfortunate operator put an end to their hopes and his fears by swallowing a mortal dose of laurel-water.

From the preceding statements it appears that alchemy constituted at the periods described a considerable branch of the medical art. It taught the preparation of a medicine which was supposed to be adequate to the cure of all diseases and to require but little skill in its application. The notion of the universal remedy is believed to have been suggested by the writings of Geber, the most ancient of the Arabian authors on chemistry, who, in detailing the process for making gold, designated the treatment of his materials by the same terms as he would have used had he been describing the medical treatment of a disease. Throughout his works he continually speaks of "the medicine," and always means some substance calculated to remedy that defective state in a base metal which is the obstacle to its being gold. This suggested to his followers that the same substance which cured an imperfect state in a metal might do the same service for a man; and hence the preparation of the universal medicine became identified with the process for obtaining the philosopher's stone, supposing both substances to be the same. Another sect of alchemists believed that they were different, and laboured at producing an elixir possessed of the desirable quality. A few instances of the virtues of the universal medicine will suffice.

An Irish gentleman, named Butler, who lived in the reign of King James I., during a voyage, had been captured by a pirate, and sold as a slave to an Arabian adept. The Arabian employed Butler in all his processes; and amongst other accomplishments, this worthy Irish gentleman learned the preparation of the universal medicine, which in this case was under the form of a stone. Being on his way home, he was imprisoned in Flanders, and there performed some wonderful cures. A monk labouring under erysipelas of a most alarming character was recovered in an hour by drinking almond-milk in which the stone had been dipped. The fame of these recoveries having reached the celebrated Van Helmont, he, along with several noblemen, came to the prison to witness some of Butler's miracles. An old woman who complained of vertigo was forthwith cured by applying to her head some oil in which the stone had been dipped: and an abbess whose arm was swollen and her fingers stiff for eighteen years was recovered by applying the stone to her tongue. These facts are attested by Van Helmont himself; it is not for me to question his veracity; every one will believe of the statement as much as he pleases: and the following account of the wonderful properties of the alkahest, or universal solvent, which he assures us he himself possessed, will assist the reader in coming to a conclusion as to his credibility. Such was the alleged power of this surprising liquor that it dissolved charcoal, metals, stones, glass, animal and vegetable substances into a liquid without any taste, and without leaving any residuum. At a time when the contest about the alkahest was warmly agitated, the celebrated chemist Kunkel, argued against the possibility of its existence; another chemist, in a conversation, put an end to all argument by asserting that he possessed it. Kunkel, too polite to contradict him, mildly inquired: "As this liquid dissolves everything, pray, sir, in what vessel do you keep it?"

The grounds on which the alchemists founded their belief of the connexion between alchemy and medicine are more explicitly stated by Glauber, a German chemist, than by any other. He doubts that the philosopher's stone converts base metals into gold, but is of opinion that it possesses the much more valuable property of removing "all distempers without distinction." He says that the ancient philosophers discovered the greatest harmony in all things celestial and terrestrial, chiefly between the sun and the metal gold, and between *man and wine:* for (says he) it cannot be denied that the life of all things proceeds from the heat of the sun: wherefore they sought to unite gold, which is the terrestrial representation of the sun, with the nature of man, by the assistance of the spirit of wine. Hence he inferred that a combination of gold with spirit of wine must be the universal medicine; these were the constituents of what was then called "aurum potabile;" and he returns thanks to God for revealing to him so great a secret. A celebrated quack medicine has in our times been fabricated of the same materials.

All this now appears far-fetched and ridiculous; yet Glauber was no mean contributor to the progress of chemistry during the first half of the seventeenth century. His methods of preparing muriatic acid and the salt which bears his name have rendered him universally known. Of this acid he assigns some singular uses: amongst others, he says that a sauce composed of muriatic acid and sugar is excellent with roast meats. He invented a sauce which, for the benefit of persons addicted to delicate condiments, ought to be made known: it is made by mixing spices, water, melted butter, and muriatic acid: and he recommends this sauce particularly to be used with an old hen, which he declares is thus rendered as tender as a chicken.

With regard to those persons who declared themselves in possession of the universal medicine, we are at no loss to comprehend in what light they are to be viewed. If they really imagined that they possessed the means of curing all diseases, it is inconsistent with our experience and knowledge of human sympathy to believe that they would wilfully withhold from the sick or the dying the relief or the respite which was thus supposed to be procurable: the failures consequent on making the trial must at once dissipate the delusion. The inevitable inference is, that such persons, especially those amongst them who had the advantage of education, were impostors who, to gratify a paltry vanity, arrogated to themselves, at no cost, an unmerited pre-eminence, and speculated on escaping the imputation of wilful imposture through the charity of those who would view their conduct as the result of enthusiasm rather than of deceit.

But if individuals thus pretending to superhuman knowledge could hope to screen themselves from public contempt by no better means than assuming the pitiful disguise of self-deception, what can be said in defence of communities or societies of educated persons who collectively professed a participation in the divine prerogative of conferring immortality, while individually they were conscious of the absurdity and impiety of such a boast.

Such a society, however, did exist; it was called the Fraternity of Rosicrucians, and consisted chiefly of physicians of the sect called chemists, or iatro-chemists. They cured diseases miraculously: looking at the patient was sufficient if he had faith. This society originated in Germany about the beginning of the sixteenth century, but excited little attention for another hundred years. The wilful perversion of their faculties, and the pretended terrors of their mysteries, are ludicrously alluded to by Butler:—

"Rosicrucian virtuosos
Can see with ears and hear with noses;
And when they neither see nor hear,
Have more than both supplied by fear
That makes them in the dark see visions."

Kircher designates their character and pretensions with very little ceremony; he calls them "Fratres qui à rosea cruce nomen habent, impium genus hominum, et diabolico commercio tumidum."

The name is said by others to be derived from Christian Rosenkreutz, a German, who, having travelled in Arabia and other oriental countries, collected a body of cabbalistic mysteries, which he disclosed to his followers under a compact of profound secrecy, and thus, they say, originated the Society of Rosicrucians. He was born towards the end of the fourteenth century; but others deny that he ever lived.

Some extraordinary enthusiasts appeared amongst this sect. John Heydon, "a servant of God, and secretary of Nature," published "A New Method for the Cure of all Diseases." His opinion was that food was altogether unnecessary, and no more than a luxury; and, for his own part, he declared that, chameleon-like, his food was pure air. Whether his solitary meditations were not enlivened with something more substantial may be matter of conjecture. John Böhmen, a shoemaker, was a renowned Rosicrucian, who wrote and published much more than any of the fraternity could understand. He died in 1624. There is an English translation of his works.

Dr. Thomson (Hist. of Chemistry, i. 173) says, "it is not at all unlikely that the greatest part, if not the whole, that has been stated about the antiquity and extent and importance of this sect (concerning which so much has been written and so little certain is known), is mere fiction, and that the origin of the whole was nothing else than a ludicrous performance of Valentine Andreæ, an ecclesiastic of Calwe, in the country of Wirtemberg. From his life, written by himself, we learn that in the year 1603 he drew up the celebrated Noce Chimique of Christian Rosenkreutz, in order to counteract the alchemistical and theosophistical dogmas, so common at that period. He was unable to restrain his risible faculties when he saw this *ludibrium juvenilis ingenii* adopted as a true history, while he meant it merely as a satire."

The Rosicrucians pretended to universal knowledge, much of which they would make the world believe was confined to their own fraternity; and along with their own mysteries they mixed up those of the Jewish cabbala. They knew all things, possessed the philosopher's stone, the alkahest or universal solvent, and the panacea or universal medicine; they could, therefore, make gold, cure all diseases, and live for ever. Cato used to say of the astrologers, he wondered how one could look another in the face without laughing: we may say the same of the Rosicrucians. They were under a rule to dispense their universal remedy and cure all diseases without reward: perhaps the doctor and patient had equal value.

The oriental metaphysics supplied the phantasies of the Rosicrucians, but variously modified. The Gnostics, according to St. Epiphanius, originated from that Simon Magus mentioned in Scripture: they believed that a vast space in the highest heavens was inhabited by beings called Œons. Some of these, along with other beings called genii, resided chiefly on earth, and were appointed to perplex the pursuits and embitter the lives of the human race. To defeat the malignant efforts of these beings, the Gnostics had recourse to magic—an art in which Simon Magus was so great a proficient that, according to some of the Fathers, he could render himself invisible, and appear again with the face of some other person; he was incombustible, and proof against injury in the fire; he could make a man out of air, and endue statues with life. He could also infest his enemies with devils, and infect them with diseases, with a few other accomplishments of less note.

The same notion of superior beings, existing unseen, yet greatly influencing the affairs of the world, is to be found in a superstition of the Persians. According to this, we are taught that before the creation of man the world had been in possession of two kinds of beings, called Peris and Dives (or Deeves), but on account of their disobedience, Adam and Eve were created, and the dominion of the world transferred to man. The Peris and Dives were, however, permitted to remain in the world in an invisible state; the former, well disposed towards man, sometimes appearing to him in beautiful and symmetric forms; and the latter, his enemies, continually tempting him. It was from these imaginary beings that the idea of the genii, which figures in the Mahometan creed, was derived.

The interference of supernatural beings in the affairs of the world was extensively believed. The Greek philosopher, Jamblichus, the most distinguished disciple of the impostor Porphyry (for in no other light can the man be viewed who, in the fourth century, would pretend to divine revelations), maintained and taught the existence of supernatural beings, whose aid could be made subservient to the private purposes of man. The means were supposed to be confined to the knowledge of the priests, who had been instructed in these mysteries by the gods, and had attained that honourable distinction by the practice of virtue and rigid asceticism. This system of metaphysics was intended to exalt the nature of man to a state of existence partaking of a mixed character, human and divine. Jamblichus himself, true to the example set by his master, worked abundant miracles, the fame of which gained for him the name of the "Wonderful and Divine Teacher." He taught the doctrines of Plotinus, founded on the Eclectic system. He died about the year 363.

These notions, or something like them, entered into the philosophy of the Rosicrucians. They believed that all space was peopled; that the four elements had their respective inhabitants, but of a kind totally different from human beings, and invisible to the uninitiated: air was peopled by sylphs, the interior of the earth by gnomes, fire by salamanders, and water by nymphs. All these beings were powerful, and their power might be made subservient to the purposes of man, one of the methods of obtaining their aid being marriage. A man married to a salamander might defy the power of fire; he that was wedded to a water nymph could not be drowned. Or the initiated could, by a spell, imprison one of the aerial spirits in a mirror, or stone, or ring; and cause it to appear, and answer questions when necessary. Thus the advantages proffered to mankind by the Rosicrucian philosophy were transcendant; and the only subject of regret was, that they could not be realized.

The founder of the English branch of this fraternity was an English physician named Robert Fludd, a celebrated chemist of that day, who, possessing universal knowledge and the elixir vitæ, and having it in his power to question the invisible spirits of the four elements in cases of doubt, must have been a never-failing practitioner. Mr. Hallam (Literature of Europe, ii., 379) thus describes him:—"Robert Fludd, an English physician, who was born in 1574 and died in 1637, a man of indefatigable diligence in collecting the dreams and follies of past ages, blending them into a portentous combination with new fancies of his own. The Rabbinical and Cabbalistic authors, as well as the Paracelsists, the writers on magic, and whatever was most worthy to be rejected and forgotten, form the basis of his creed." In 1616, he published a history and defence of the fraternity, which caused a con-

siderable sensation; and from that time its establishment in England may be dated. According to a ridiculous custom which prevailed in these days of Latinizing names, Fludd metamorphosed his into Robertus a Fluctibus—a kind of miserable pun upon Fludd (flood).

The skill and knowledge of this grand master of the Rosicrucian philosophy may be appreciated from a wonderful cure performed by him on a patient afflicted with a relentless gout. The doctor directed a dog to be laid in bed with him; the patient got well; but the luckless dog acquired the gout, and ever after was subject to the same periodical fits which formerly afflicted his master. Nor is this remarkable cure so much to be wondered at when we have it on the authority of Riverius, a professor in the University of Montpelier, that a lady suffering under the torture of whitlow was directed by him to put her finger into the cat's ear, and to keep it there until relieved: in two hours the lady was without pain, but puss suffered in her place. This was called Transplantation, and many cures are reported to have been effected by it; such as applying a dog to the cheek of a person labouring under toothache; the patient gets well, but the dog goes howling about with the pain.

There was a mode of cure much relied on during the period of alchemistic medicine which ought not to be passed by; it was used in cases of wounds inflicted by a weapon, the medium being an ointment called the weapon-salve: its efficacy has been insisted on by Van Helmont and Paracelsus. The peculiar advantage attributed to this remedy was that it acted at a distance; for if the instrument which inflicted the wound were anointed with the salve, the wound almost immediately healed. Modern surgeons have not treated this improvement with due deference when they substituted the plan of applying the plaster to the wound instead of the sword.

Let us turn away from these insane vagaries and moral hallucinations, by ministering to which the character of the physician was compromised, and let us glance at the healing art during a revolution which greatly enhanced its dignity and utility.

If the vain pursuit of the three grand secrets, the philosopher's stone, the universal medicine, and the universal solvent ruined, instead of leading to fortune, all those infatuated beings who engaged in it, their labours enabled them to bequeath to their successors a rich legacy of dearly purchased knowledge. The alchemists, with the most persevering industry, submitted everything that came under their observation to a multiplicity of processes, and during these researches discovered an abundance of new substances which, not possessing the properties so much desired, were passed by as things of little import. When men at length perceived the falsehood of the three grand propositions—that all metals are essentially the same; that the life of man may be indefinitely prolonged by art; and that all matter may be dissolved by one agent,—they relinquished the end as unattainable, and began to collect the hitherto neglected objects. They now found that these were the only real rewards of their labours; the delusions of alchemy were dissipated; and then commenced the sect of the iatro-chemists.

The appearance of the iatro-chemists was the proudest era at which the healing art had ever arrived. The discovery of new therapeutic agents possessed of great energy ensured them adoption in preference to the feeble remedies which had been for centuries in use. From the earliest ages physicians had recourse to simples only: Hippocrates and his commentator Galen, knew scarcely any others. It is observed by Pliny that throughout the numerous writings of Hippocrates we find him prescribing herbs only; that Diocles, next to him in succession and reputation, used the same simples; that Praxagoras, Chrysippus, and Erasistratus, followed the example; and that Herophilus, who introduced a more refined kind of practice, esteemed simples as much as any of his predecessors.

When the chemical physicians began to attract notice they denominated themselves chemists or iatro-chemists; while those who still exclusively used simples, and adhered to Galen's hypothesis of qualities, were designated Galenists.

The Galenists, for ages in quiet possession of the confidence of mankind, at length began to suffer from one of those revolutions which the sciences have so often experienced after great political convulsions. In the year 711, the Saracens had invaded Spain, and being victorious they maintained a settlement until 1492, when they were expelled from Grenada, the last province which they possessed. During their occupation, under the mild dominion of the Caliphs, Spain enjoyed commercial prosperity and domestic happiness: it was one of the most enlightened of the Mahometan states. While the Christians were plunged in profound ignorance, the Saracens gradually introduced amongst them arts and sciences which they had preserved during the intellectual slumber of the dark ages. Spain became a great nation: the capital of the Saracen empire Cordova, contained 900 baths, and a mosque which numbered 1000 marble columns. At the close of the tenth century it possessed 600 temples, 80 free schools, and 200,000 houses. The Caliph Alkahen converted his palace into an Academy which was then the most celebrated in the world; he collected from all parts of the world a library consisting of 600,000 volumes, the repository of all the learning of the age (Prescott). It was the resort of persons eminent for literature and science; and produced many distinguished men and women. The physicians educated in this academy studied chemistry, then sedulously cultivated by the Saracens, introduced into their practice various preparations drawn from the mineral kingdom, and used sublimations and distillations. The high authority of the Saracen physicians gave popularity to chemical remedies, and hence the chemical practitioners of medicine spread all over Europe.

The chemists by this innovation on the old practice drew on themselves not only the opposition but the hostility of the Galenists: animadversions, ridicule, and actual abuse, were largely dealt in by both parties; and a contest was carried on for nearly two centuries, in which was evinced more virulence than an honest search after truth. The Galenists, who at least were men of learning, boasted that the herbs and simples used in their practice were congenial to the human constitution, and that the patient incurred no danger from violence in the operation of their remedies. The chemists replied that, through the want of activity in these simples, the patient was made to incur still greater dangers than by the active practice to which they were opposed; that to die by inert treatment was in effect no worse than to be killed by the adoption of energetic means; that so far both sides were on a footing; and that the advantage lay on the side of the chemists by the more speedy cures which their measures effected, and by their success in cases which their antagonists could not undertake with any hope of success. They further declared that the management of the conserves and confections of the Galenists might be very fit for cooks, but was utterly derogatory to physicians. Dr. Kirkringius, a strenuous supporter of the chemical school, declared the Galenists to be so ignorant that "they contemned every sublime preparation of the chemists, proscribing them as unprofitable, perilous, and hurtful:" and on account of the unreasonableness and violence of the Galenists, he thinks it is not strange that the chemists should retaliate with vehemence.

With vehemence, indeed, they did retaliate; a violent and long-continued contest gave vent to the fury of the belligerents, which at length terminated in favour of the chemists. This important victory over ancient prejudices is to be chiefly attributed to the appearance in the world of an extraordinary person, a man who, while he unintentionally assisted in the extinction of superstitions in medicine, was their professed and firm supporter; and who, by his own discoveries and application of the discoveries of others, gave to the science of chemistry an *éclat* which it had never before possessed. Of this remarkable character some account ought here to be given.

(To be continued.)

PROCEEDINGS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Mr. Hodgson, President, in the chair.

CASE OF POPLITEAL ANEURISM TREATED BY COMPRESSION; WITH REMARKS, AND A LIST OF THE CASES TREATED IN DUBLIN.

By O'B. Bellingham, M.D., F.R.C.S.I.,
Surgeon to St. Vincent's Hospital, Dublin.

The subject of this case was a labourer, aged 42, who was admitted into St. Vincent's Hospital, under Mr. Bellingham's care, in November, 1850. The aneurism, which was of large size, was seated on the right side; had a strong heaving impulse, and a short, harsh bruit was heard on auscultation over it. The treatment was commenced by placing the patient upon a very restricted diet, particularly as regards fluids (six ounces only being allowed in the day, with eight ounces of solid food), confining him strictly to the horizontal posture, with a dose of purgative medicine each night. Under this treatment, continued for some days, the pulse, from being hard and incompressible, became soft, small, and slow. Compression was commenced December 4th, at eleven a.m., by means of two instruments, one upon the artery where it crosses the ramus of the pubis, the other at the lower third of the thigh. At half-past eight p.m., the outlines of the aneurismal sac were more distinct; the patient's skin was cool, and he did not complain of pain. He remained awake during the night, and kept up the compression himself, the points upon which the pad of the instrument should rest having been marked with ink. Next morning, between nine and ten, on unscrewing the instrument, the pulsation of the aneurism was found to have ceased; the tumour was hard, solid, and circumscribed, and an enlarged collateral vessel was felt over the centre of the popliteal region. Moderate pressure was continued for some days; the patient was kept in bed, and the diet was gradually improved. The tumour diminished in size, and became harder, and when the patient returned home, the limb was as strong as the other, and his general health perfectly good.—Some remarks upon the treatment of aneurism by compression followed, in which the author contrasted the results of compression and the ligature, and pointed to the advantages likely to ensue from combining constitutional with local treatment. In a table appended to the paper, the author has given a list of all the cases of external aneurism treated by compression in Dublin during the last seven years, in which the seat of the disease is mentioned, the hospital or other locality where the treatment was conducted, the surgeon's name who had the management of the case, and the results are stated. Of these, it appears that twenty-six were cases of popliteal aneurism, twenty-one of which were cured; six were cases of femoral aneurism, of which five were cured, the sixth having been a form of traumatic aneurism, in which amputation of the limb was the only resource. Three were cases of brachial aneurism, of which two were cured; in the other, a high bifurcation of the brachial artery existed, and two vessels required to be tied. One was a case of radial aneurism, which was cured by compression. Of the remaining five cases of popliteal aneurism, amputation of the limb was performed in one, the patient recovering; in a second, the ligature was used with success; in a third, the patient was obliged to return to his employment before the cure of the disease; the aneurism diminished in size, and the patient continued to work for above three years afterwards, when symptoms of aortal aneurism supervened, under which he sank. In a fourth, the patient died of pulmonary disease, and the fifth patient, who was of a broken-down constitution, died of erysipelas.

ACCOUNT OF THE DISSECTION OF A CASE IN WHICH TWO POPLITEAL ANEURISMS HAD BEEN TREATED BY COMPRESSION OF THE FEMORAL ARTERIES.

By P. Hewett, Assistant-Surgeon to St. George's Hospital.

A man, aged 38, was admitted into St. George's Hospital, in the middle of 1848, under Mr. Cutler, with an aneurismal tumour in each ham. That on the right side, completely filling this region, was compressible, but could not be emptied; that on the left, not larger than a small egg, was hard, and to a great degree apparently solid, and with much less pulsation. The tumour on the right size had only existed three months, and nothing had been done for it. From the account of the patient it appeared that the disease on the left side, which had begun about eighteen months back, had been treated by compression of the femoral artery, at the Wexford Infirmary, where the pressure had been kept up, more or less, for seventeen weeks, during which time the limb had regained its natural size, and the tumour was reduced to its present state, from which it has never since varied, and has caused him but little inconvenience. His general health, which had begun to give way about two years and a half back, had prevented him from following his business of musical instrument-maker. When admitted into the hospital he was pallid and apparently suffering from great debility. At a consultation of the surgeons, it was determined, under existing circumstances, that compression should first be applied to the right femoral artery, and the instrument, a ring tourniquet, was so adapted as only to lessen the circulation in the limb, and to be worn for a few hours daily. In some little time the limb was reduced in size, and the tumour became smaller and firmer, but pulsation still remained. Some six weeks after his admission, and whilst under surgical treatment, cough and expectoration, with difficulty of breathing, made their appearance. Auscultation detected nothing abnormal about the heart, but the lungs were found to be engorged at the back part. The chest symptoms went on increasing in severity, and the patient one day suddenly brought up a large quantity of arterial blood, and died shortly afterwards. The tumour in the right ham had gone on decreasing in size, and had become firmer and more solid, but some pulsation was still felt. No change had occurred in the left ham.

At the examination of the body, which took place thirty-one hours after death, the left aneurismal tumour, deeply imbedded in the popliteal space, was found lying between the joint and the artery, of the size of an egg; it was pyriform in shape, and apparently quite solid, but on cutting into it the lower half only was filled with long-standing coagula; the upper part still presenting a cavity lined throughout by a perfectly smooth membrane continuous with the coat of the artery, merely contained some small recent clots. Of the two openings into the sac, the upper one was large, and nearly of the size of the artery; the lower one, on the contrary, was much contracted, and scarcely admitted a common sized probe. The portion of the artery lying upon the sac was also very much contracted, but its coats were healthy, as well as those of the posterior and anterior tibial vessels, which were of their normal size. In the upper part of the popliteal, and in several parts of the femoral, there were large patches of atheroma, with three distinct aneurismal dilatations, one in the former vessel and two in the latter. The femoral artery and vein were pervious in their whole length, and the surrounding cellular tissue was not thickened. The vein and the nerve in the popliteal space were firmly adherent to the sac with a few of the fibres of the gastrocnemius muscle. The aneurism on the right side, larger than a cricket-ball, was also lying between the artery and the knee, to which it was firmly adherent. It was filled with laminated coagula, save at the back part, where there was still a small channel leading from the upper into the lower part of the vessel; this channel was rough throughout, and covered with recent fibrine. The upper opening of this channel was free and smooth; the lower one was small, and below it the artery was reduced to the size of the posterior tibial. Above the aneurism the coats of the artery were much thickened by atheroma, and here too, about an inch and a half above the tumour, was another small aneurismal dilatation. The femoral artery presented several patches of atheroma, but it was otherwise healthy, and, as well as the

vein, pervious throughout its whole course: the surrounding cellular tissue was not thickened. With regard to the popliteal vein and nerve, the appearances were the same as those observed on the left side. The thoracic aorta was extensively affected with atheroma throughout a great part of its course, and it was somewhat dilated. In its arch, it presented three distinct aneurisms, one of which, the largest, was lying between the large vessels and the windpipe, into which it had burst by a small ulcerated opening, about an inch above the bronchi: the cavity of this sac was partly lined with long-standing coagula. The bronchi were filled with blood, in addition to which the lungs themselves presented several large patches of pulmonary apoplexy, and were extensively affected with emphysema. All the abdominal organs were healthy, excepting the kidneys, which were somewhat smaller than natural, rough on their surface, and with several small cysts in their structure.

A pause having ensued after the reading of the papers,

Mr. Macilwain rose and said that the papers were too important to be allowed to pass without discussion. He rose, however, more for the purpose of eliciting information than to impart it. He proceeded to speak on the subject of the treatment of aneurism generally, and said that we appeared to have stood still in the matter since the days of Hunter. Had Hunter lived, no doubt many of the inquiries into the pathology of aneurism since undertaken, would have occupied his attention, particularly the cause of the deposition in the artery and other points in connexion with the subject. Mr. Macilwain then proceeded to speak of the importance of having more accurate reports of the cases which were subjected to treatment, and expressed his opinion that we regarded the disease too distinctly as a local one.

Mr. Hodgson was obliged to Mr. Macilwain for the observations which he had made, but he thought that the discussion should be confined to the subject immediately under consideration,—viz., the cure of aneurism by compression. The consideration of the morbid changes taking place in the vessels in aneurism might be well discussed on another occasion, but on the present we should limit ourselves to the points embraced in the papers just read.

Mr. Partridge thought the most desirable plan to pursue in the discussion was for the surgeons who had had any experience of the treatment of aneurism by compression, to state the result. He was inclined to think that the London surgeons were open to the remark of Dr. Bellingham, of having neglected the plan under consideration. He (Mr. Partridge) could speak for King's College Hospital, that pressure had been but little employed in that institution, and the result was by no means encouraging. This was partly attributable to the imperfect instrument employed, and partly to the circumstance of the patients being entrusted a good deal with the treatment themselves. Thus, a stout healthy-looking man was admitted into the hospital with a popliteal aneurism, and the management of the instrument was mainly left to himself. He screwed up the instrument so tightly that it eventually broke, but not until a large slough formed on each side of the aneurism, which remained in the same state. A ligature was afterwards applied; the man lost his toes by gangrene, but the aneurism was cured. If he (Mr. Partridge) had such an instrument as that exhibited on the table he should use it, as it was a great improvement on the one usually employed in London. He inquired the experience of surgeons on the state of the artery after compression had been employed unsuccessfully; it having been urged by some that the artery, after the failure of compression, was not in so favourable a condition for the application of a ligature as before.

Mr. Quain said that Mr. Partridge's case could not be taken as the type of those he had seen. He had observed good results from the treatment by compression in a few cases of popliteal aneurism, and he was favourably disposed to that plan of treatment. He feared that a portion of the remarks in the paper first read were not calculated to conciliate support to the practice it advocated; he alluded to the remarks made in connexion with the statement that surgeons out of Dublin "decry" compression as a mode of treating aneurism. This statement, too, he believed to be erroneous; at least, he had not heard anything that would bear it out. But the question really was not, what is thought in Dublin, or in Edinburgh, or in London, but what was the fact as to the utility of compression in the management of the disease. While he listened to the paper he was struck by the circumstance that no mention was made of the treatment in question being resorted to in aneurisms, other than the popliteal and femoral. He (Mr. Quain) had seen the late Mr. Liston use compression of the brachial artery in a case of aneurism of the hand from injury. Though the compression was made under favourable circumstances (for it was well applied, and the patient gave every aid to the surgeon), still it entirely failed. The disease in this instance was cured by ligature of the brachial artery. In the operation, this artery was by no means so easily secured as it usually is, owing to the thickening of the cellular substance and fascia by the compression; but there was no such difficulty in the case as would justify, in his opinion, any opposition to the use of compression upon that ground. He thought at the time that the want of success in this instance might perhaps be attributable to the large nerve which courses over the brachial artery. The femoral artery, it will be remembered, has no nerve of magnitude in company with it. Dr. Bellingham, moreover, gave no account of the condition of the parts upon post-mortem examination after the successful application of compression, but Mr. Hewett had this evening given the history of such examination in one case. He himself had witnessed one dissection in which the femoral vein was found to be obliterated.

Mr. Partridge said that the statistics should state whether the patients were cured or not, and how long they had remained well. He thought that Dr. Bellingham was right in saying that in London we did not habitually employ pressure, and that there must be some reason for it.

Mr. Quain had seen compression employed successfully in cases of femoral and popliteal aneurism, but at the moment he did not recollect the number of cases.

Mr. Partridge suggested that Mr. Curling should state the experience of the London Hospital surgeons, and Mr. Cock that of the Guy's men, of compression.

Mr. Prescott Hewett differed with Mr. Partridge respecting the employment of compression by London surgeons; at all events he could speak for St. George's, for scarcely a case of aneurism was admitted into that institution in which compression was not at first resorted to. During the last three or four years there had been five cases of aneurism in the hospital, including the one detailed in the paper before the society. Two of these were cases of popliteal aneurism, one of which was of very large size. In both cases compression was applied to the femoral artery, but in each instance, owing to some peculiarity in the patient, compression was discontinued, the artery was ligatured, and both cases did well. The instruments employed were not so clumsy as had been represented: in both cases compression was kept up by two tourniquets in two parts of the artery. The patients were under the care respectively of Mr. Cæsar Hawkins and Mr. H. C. Johnson. In neither of the cases did the effects of compression render the application of the ligature more difficult. The third case was one of diffuse aneurism of the ulnar artery, consequent upon a wound; in this case the tourniquet was applied over the brachial. He did not think that the failure in Mr. Liston's case of aneurism in the hand was attributable to the contiguity of the nerve to the brachial artery: for in the case in St. George's, the pressure was applied over the brachial, and the patient was cured in a fortnight. In the fourth case compression was tried, and acted apparently with good effect; but in two or three months the pulsation was again detected; the patient was unwilling to submit again to pressure; the artery was consequently ligatured, and a cure effected. The fifth case was the one

related in the paper before the society. In answer to Mr. Partridge respecting the influence of compression on the after operation of ligature, he might say, in the case operated on there was no thickening of the sheath surrounding the vessels.

Mr. Curling had no information to give on the subject, as he had had no case under his own care; but he had no disinclination to try compression when a suitable case presented itself. He was quite satisfied that it was a valuable plan of treatment, and thought the society indebted to Dr. Bellingham for bringing it forward. He regretted, however, that Dr. Bellingham had not given more information as to how and where he applied pressure. The instrument on the table was not sufficiently known in London; his colleague, Mr. Ward, had to send to Dublin to procure one. He thought, in cases of compression on the femoral artery, obliteration of the vein, as in the case mentioned by Mr. Quain, might be avoided by having the pressure applied either just above or below Poupart's ligament. The instrument required management. Where did Dr. Bellingham apply pressure on the femoral artery? He thought Mr. Quain's observations respecting the brachial artery would be borne out by other cases. The pain would be very severe from pressure upon the nerve.

Mr. Macilwain having offered a few words of explanation, and declaring that he had no desire to offer any irrelevant remarks,

Mr. Cock rose and said he regretted that his experience of the employment of pressure was limited to two cases of popliteal aneurism. In these cases, the only reason he believed the plan did not succeed was, that the patients did not persevere in the employment of the means—one discontinuing it in four, the other in six days. There was no reason to doubt that if the patients had gone on they would have got well. The instruments employed in Guy's Hospital were by no means so perfect as the one on the table, and were more irksome. In each of the cases to which he had referred, the femoral artery was tied at the urgent request of the patient. Both patients got well; but in one case the operation was rendered somewhat more difficult from some thickening and inflammation of the sheath of the vessels. Beyond this the pressure had not interfered with the application of the ligature. He (Mr. Cock) had no doubt that the failure of the pressure in these cases, and the inability of the patients to bear it for any length of time, had arisen from the clumsy character of the instruments, and the bad manner in which they had been applied. The patients in these cases had not been sufficiently watched, and were seen only daily or every second day. Much more watching and care was required in the proper management of these cases than were usually bestowed on hospital patients, and to a neglect of these the failure in the cases he had related might fairly be attributed, as well also to the neglect of instructing the patient carefully in the mode of applying the pressure. He thought, however, that pressure in the treatment of aneurism would soon be much more extensively employed in London than it had been.

Mr. Athol Johnson said that three cases of aneurism which had been treated by pressure had been in St. George's Hospital during the period that he was house-surgeon to the institution. Two of these were cases of popliteal aneurism, in which pressure was applied over the femoral artery, but in so clumsy a manner, and with such clumsy instruments, that the plan failed in both cases. The vessels were afterwards tied, and the patients did well. The third case he believed was one of those mentioned by Mr. Hewett, of aneurism of the ulnar artery, in which judicious pressure, modified by a suggestion of his own, soon effected a cure.

Mr. Hodgson hoped, if Dr. Bellingham were in the room, that he would give some further particulars of his mode of treatment. He thought the profession in England were much indebted to their Dublin brethren for the great attention they had bestowed on the treatment of aneurism by compression, and to the improved method they had carried out. They had developed the principle on which the practice was undertaken. Three modes of treating aneurism by pressure had been resorted to. The first, that introduced by Bottani, consisted in bandaging up the limb to a point beyond the swelling, and thus compressing the vessel: some cures, but very rare, were effected by this mode. The second plan was the employment of severe pressure on the vessel, at a distance from the disease, so as to prevent entirely the flow of blood through the artery. This plan had been adopted by Mr. Frere of Birmingham, and the pressure seemed to act on the artery as if it were ligatured. But this plan caused so much suffering that it could be borne in only a very few cases, and it was rarely successful. In the few cases in which he (Mr. Hodgson) had seen it attempted, the pressure could not be borne. It was reserved for the Dublin surgeons to resort to a moderate degree of pressure, long continued, for the cure of the disease. There was a great physiological principle involved in this plan of treatment. If moderate pressure were long continued, the stream of blood through the vessel became diminished, the vessel became constricted, the circulation through the sac became less, a deposition from the blood took place in it, and a cure was effected. In looking at Mr. Hewett's case, read before the society, he (Mr. Hodgson) should consider it doubtful if the cure could be said to be permanent; for though the sac was partly filled with a coagulum, and the aperture diminished, there was still such a cavity left, that it was likely that the aneurism might return if the circulation had been much disturbed. He would inquire if, in Dr. Bellingham's cases, there had been any secondary aneurism, and also the state of the vessel in those cases in which the patients had died of other diseases. We were not only indebted to the Dublin surgeons for the mode of compression which he had spoken of, but they had rendered compression much less irksome by the form of apparatus which they employed, and their substitution of an elastic material, like India-rubber, for an inelastic one. Another point alluded to was the application of pressure at two distinct points, so that pain and weariness might be prevented by changing the place of pressure. It had been said by some that compression was only applicable to the femoral artery; but he might observe, that if a ligature on the distal side of an aneurism might cure, there did not appear any good reason why pressure applied on the distal side also, might not act effectively. If so, pressure might be applicable in cases in which it was impossible to apply it on the proximal side of the aneurism.

Dr. Bellingham was now called upon to reply, but spoke in so low and indistinct a tone as to be quite inaudible during most of his speech. We understood him to commence by thanking the society for the manner in which they had received his paper; and he then referred to some casts on the table of a limb before and after pressure had been applied to it, to cure aneurism. He then mentioned some cases in which aneurism had been cured by compression. In one case, the aneurism—a popliteal one—was cured in twenty-four hours; but an aneurism of the opposite side presented itself, and took a much longer time to cure. The patient eventually died from aneurism of the descending aorta. The artery over which the pressure had been applied was found to be quite normal; the aneurism was obliterated; the vein was normal. In another case, in which pressure had been applied to the femoral artery for popliteal aneurism, galvanic punctures having been also employed, the patient had died at the end of ten days, from erysipelas. The aneurism was found nearly filled by layers of fibrine; the artery under the seat of pressure was healthy. He had dissected a patient who had suffered from aneurism in both popliteal arteries. One of these was treated by compression; the other, by ligature. The latter returned at the end of three or four years; not so the former. The vein and artery were found healthy. It was difficult to apply pressure to the femoral artery without involving the vein in the compression. In almost every case which he had treated by compression, the pres-

sure had been made at two or more points. He begged to say that his observations referred more to the Edinburgh surgeons than to those of London, on whom he had no wish to reflect. In the list of cases which had been alluded to in the reading of the paper, but had not been fully read, instances were recorded in which the radial artery was the seat of aneurism, and which had been cured by pressure made on the brachial artery. After once more thanking the meeting, Dr. Bellingham sat down, amid much applause.

MEDICAL SOCIETY OF LONDON.—May 31.

Dr. Murphy, President.

SWALLOWING COPPER COINS.

Dr. Webster related the case of a girl of five years old, who swallowed a copper token, the size of a farthing, which remained nearly two days in the alimentary canal without producing any serious consequences. In this patient, the accident not having been discovered till upwards of eight hours had elapsed, it seemed injudicious, in Dr. Webster's opinion, to give an emetic of ipecacuanha, which he at first thought of, in order to produce vomiting, and thereby eject the foreign body. Thinking the coin might have by that time passed through the pylorus, aloes and rhubarb were therefore prescribed, followed by castor oil; strict injunctions being given, at the same time, to avoid everything acid, whilst bland and liquid food only was permitted. Although free purging was produced, no beneficial effect followed; whereupon, several doses of senna and salts were ordered, and the same regimen continued. By this treatment, at the end of forty-four hours, the piece of copper then shown to the fellows was fortunately expelled from the rectum, without having produced any untoward symptom, when the patient soon became convalescent. Notwithstanding there was nothing very remarkable in the case brought under the society's notice, still, having terminated favourably, Dr. Webster thought it of sufficient interest to merit record, especially as similar accidents occasionally occurred having a fatal termination. Besides, different authors, to whom reference could be made, if necessary, in support of the above opinion, the last weekly report of the Registrar-General was mentioned, seeing a somewhat analogous instance had been met with at Crown-square, Camberwell, which proved fatal. The subject was a labourer's daughter, aged three years, "who died of mortification of the bowels by metallic poison, from swallowing a farthing accidentally." The result recorded in this case not only indicated the danger produced by copper when swallowed, but made the narrow escape of the other juvenile patient more gratifying.

Dr. Ogier Ward related a case in which a copper coin had been retained in the œsophagus of a child for eight months. The chief symptom was a profuse flow of the saliva. When extracted, the coin was so much corroded as to be scarcely distinguishable as a halfpenny. In another case which he had seen, a copper halfpenny had been retained in the œsophagus for four days: there was here also a profuse flow of saliva, but the coin was not corroded when extracted.

Mr. Dendy had met with very many cases in his public practice in which copper coins had been swallowed by children. The result of his experience was that they did no harm, nor did he see that we had reason to expect that they would.

Mr. Taylor read a paper on the

TREATMENT OF FEBRILE AND OTHER DISEASES THROUGH THE MEDIUM OF THE CUTANEOUS SURFACE.

The author began by alluding to the great mortality of fever, typhus, scarlatina, and measles in this country, which called for serious consideration. He then entered into a history of several such cases, in which he had been enabled to trace out that the agent which contributed greatly to the recovery of such patients, was lardaceous inunction. It allayed the dryness of the skin and promoted perspiration, producing sleep. He then entered largely on the subject of the function of the skin, and the noxious effects resulting from the arrest of its secretion upon the animal economy, and the good effect produced in the course of many diseases by the restoration of its function. The author then entered into a comparison between cold affusions or water-sponging and lardaceous inunction; the first being, in most cases, but temporary, and not unfrequently attended by danger. He then gave the history of cases of measles, fever, and scarlatina, illustrating the happy results of inunction; and concluded by strongly recommending this course of practice, not to supersede other means, but as one of the most powerful adjuvants he was acquainted with.

In the discussion which ensued various fellows took part. Was the plan recommended novel? It was contended that it was not so, and Celsus was referred to in evidence. But this was met by a counter-statement that Celsus had never recommended oil in the mode practised by Mr. Taylor; but merely a mixture of oil and water to be rubbed on the surface to cool it. In fact, oil was used generally by the ancients in most diseases. Had the oil any effect *per se*? It was generally considered that the real benefit in cases where Mr. Taylor's plan was employed consisted in the friction resorted to, and cases were detailed in which soap suds, and even sand, had been used with good effect. One speaker had employed Mr. Taylor's plan with much benefit, but he had not neglected the ordinary indications of treatment in the instances in which he had resorted to it. It was generally considered that the application of water, while at the same time it was more cleanly, would be found more efficacious; and very severe comments were made by some of the speakers on the practice which seemed to obtain of late, of vaunting some peculiar plan of treatment as a panacea in the cure of disease, whilst the more legitimate modes of practice were neglected. The evils of such proceedings were incalculable, as they not only obstructed the course of legitimate inquiry, but tended to throw discredit generally on the practice of scientific medicine. The author in his reply declared that he had brought the subject before the society in order to give his plan of treatment publicity, and to induce others to give it a trial, and decide upon its effects by their own experience. Far from bringing it forward as a panacea, he begged to say that he never neglected the mode of treatment by medicines which was indicated by the symptoms; but in cooling the skin, in inducing perspiration and sleep, he had found frictions on the surface, with the ointment he had named, far superior in their effects to any other mode he had employed. The treatment, however, was only auxiliary to other remedies, and as such he begged to recommend it to the notice of the profession.

This being the last night of the session, the president made a few congratulatory remarks on the success of the past session generally, and referred to the importance of fellows forwarding their papers early to the council.

PATHOLOGICAL SOCIETY OF LONDON.

Dr. Latham, President.

Dr. Quain presented

LUNGS SHOWING THE ARREST OF PHTHISIS IN THE THIRD STAGE OF THE DISEASE.

A female, in May, 1848, when thirteen years of age, was admitted an out-patient at the Brompton Hospital. She was very delicate, had lost flesh, and was suffering from severe cough, shortness of breathing, &c. Her illness had commenced with influenza in the early part of the preceding winter; she had also suffered from an abscess in the right arm. She had been recommended cod-liver oil, but was unable to keep it on her stomach. There was no predisposition to phthisis, and she had not then had hæmoptysis. Since that time a younger sister has shown unequivocal evidence of phthisis, and an older sister has now become delicate. A note, taken shortly after her admission, states that "there is extensive consolidation at the apex

of the left lung, and some deposition at the apex of the right," shown at the one side "by decided dulness, bronchial breathing, and bronchophony; and at the other side, by a feeble inspiratory, and a prolonged louder expiratory murmur."

A mixture, in which a drachm dose of cod-liver oil was diffused by means of liquor potassæ in mucilage, and a syrup composed of mucilage, syrup of squills, and a minute dose of morphia, was prescribed. The oil mixture was taken without disturbing the stomach, and she kept her ground. Examined in August she is stated to have lost four pounds in weight, and crepitation is heard over the left apex; nothing additional at the right apex. Iodine counter-irritation was then applied. In the beginning of September she had profuse hæmoptysis, and subsequently a free puriform expectoration.

An examination, made in the course of this month, when she was able to attend the hospital, showed the existence of a large cavity, where the consolidation and softening had been previously observed. The dose of the oil was subsequently increased, first to a drachm and a half, and then to two drachms, with advantage; for in the end of the following December, it is recorded that "she gains strength, and coughs but little." She did not attend during the winter, but received her medicine by her mother, and did well. In April, 1849, she had an attack of influenza, from which she soon rallied.

In the following June the record is, that "she has not lost ground, though she has not gained in weight since her admission a year ago; there is loud pectoriloquy, cavernous breathing, and gurgling at the left apex, and loud expiratory murmur at the right." At the end of July the report is, "she looks well, coughs only in the morning." In August an examination showed "flattening of the chest over the apex of the left lung. The respiration there, though cavernous, is not loud. The pectoriloquy is very distinct. The respiration at the right apex is somewhat puerile." During the winter (1849–50) she continued the remedies. In February her appetite had failed, and a mixture of infusion of gentian and bicarbonate of soda was ordered once a day. From this she derived so much benefit that it was continued three times daily, and she was able to take the simple aniseed oil in half-ounce doses. The following June it is noticed that she has had an attack of nettle-rash, but is still gaining strength, grows tall, and coughs but little, and only in the morning.

This improvement continued; and it is noted that last October she came to the hospital, having been for some time in the country, looking extremely well. Her weight, which at one time had been as low as four stone two pounds, is now four stone nine pounds. She had scarcely any cough; her appetite is good. She is free from suffering of any kind. Examination of the chest shows remarkable flattening and contraction over the apex of the left lung. There is very evident dulness in this situation, and the mobility here is as 9 to 32 of the opposite side. The respiration is of a sharp whiffing character, with slight crepitus. At the opposite side the respiration is loudly puerile, and percussion shows the right lung extending across the sternum to the left side. At the summit of the left lung posteriorly the respiration is scarcely audible. The dulness here is more decided than in front. The heart is seen and felt to beat distinctly from between the second to the fourth left costal cartilages. The action of the heart in this situation had been a source of some annoyance to her. From this time (October) to the commencement of last March, this improvement continued. Her cough had nearly if not altogether disappeared. She continued the gentian with soda, the cod-liver oil, and the counter-irritant occasionally. At the beginning of March, during the prevalence of the influenza, she was attacked by the gastric, and not the pulmonary, complication of the disease. It commenced with bilious vomiting, followed by diarrhœa, great prostration, and rapid collapse, from which she died on the fourth day.

The body was well proportioned, and showing a very fair amount of fat in the subcutaneous tissue. The right lung was seen to be very voluminous, and extending across nearly as far as the left margin of the sternum. There was no appearance of the left lung in front, but its place was occupied by the heart and pericardium drawn upwards and to the left side, and the walls of the apex of the chest falling inwards and downwards. The heart was healthy, and rather large for the size of the body. The left lung was found much diminished in size behind it. The lung was adherent more especially at the apex, which was covered posteriorly by a mass of solid fibrinous tissue, corresponding to the seat of dulness and feeble respiration previously mentioned. Very nearly the whole of what had been the upper lobe of this lung was occupied by the remains of a cavity irregularly divided into two by one of the bands so frequently seen in phthisical cavities. The entire cavity was about the size of a large walnut. It contained about half a drachm of a thin whey-like fluid, with which were mixed particles of whitish coagula. The walls were formed by condensed pulmonary tissue, varying in thickness from less than a line to a quarter of an inch, and in some points puckered and contracted. The air-cells and small bronchi were distinctly visible, under the microscope, in this tissue, which was separated from the contents of the cavity by a wall or membrane composed of firm filamentous tissue and granular cells. This membrane had much the appearance of a mucous membrane, but it was not examined sufficiently soon after death to be able to trace the presence of an epithelium. The cavity communicated with the left bronchus by an orifice which would admit a crow-quill, situated midway between the top and bottom of the cavity. There was a good deal of healthy respiratory tissue in the lower lobe of this lung; but there were scattered through its substance six or seven points of condensation, such as are hereafter described existing in the right lung. The right lung was large, and the air-cells partook of its character. In water it displaced a quantity which measured twenty-three ounces, whilst the left displaced but nine ounces. The apex was remarkably puckered; and on cutting through this puckering, the tissue of the lung was found to be traversed by short fibrous bands, between which appeared points of softish pale-yellow tubercle. A little lower down in the centre of the upper lobe a mass of soft tubercle, about the size of a small hazel nut, was found. It was enclosed in a cyst, and consisted almost entirely of fatty granules and cells containing similar particles. In the other lobes several consolidated points were found—the largest smaller than last described, and none so fully formed. They appeared in some places to consist merely of condensed tissue; in two there was an appearance of yellow, firm tubercle; and in two, small calcareous particles. In neither lung was there the least appearance of recent tuberculous deposit. The other organs were healthy; the kidneys were large. There was no disease of the intestine beyond congestion, which in some parts was very distinct.

This case affords an additional illustration of the great extent to which the ravages of pulmonary phthisis may proceed, and its progress yet be stayed. Such cases were, happily, now met with more often since cod-liver oil had come into use; still Dr. Quain did not know of any case which afforded, by the evidence of post-mortem examination, so striking a result. This case was also interesting from its throwing light on the nature of the puckerings so constantly seen. Some observers were disposed to regard them as being independent of tuberculous deposit. In this case it was evident that they were due to the previous existence of this deposit, which, in fact, had been recognized there during life, and traced after death.

THE CENSUS, 1851.—Total population of England, Wales, and Scotland, including the Channel Islands, amounts to 20,919,531 persons; of whom 10,184,687 are males, and 10,734,844 females. The population of London is 2,363,141; of whom 1,104,356 are males, and 1,258,785 females. The most remarkable fact in the return is the great proportionate increase of females. In 1841 there were 493,303 more females than males; now the excess is 550,157. In 1841 the excess of females in London was 124,367; now it is 154,429.

CASE OF APOPLEXY TERMINATING FATALLY, IN WHICH THE CÆSAREAN OPERATION WAS PERFORMED WITH A FAVOURABLE RESULT TO THE CHILD.

(Communicated by E. M. Hodder, M.D., M.R.C.S.Eng.)

Mrs. D., aged 36, stout muscular figure, and plethoric habit, in the commencement of the ninth month of her sixth pregnancy, called and requested my attendance in her approaching accouchement, which she expected to take place at the end of the month (June). She had always enjoyed good health, her previous labours having been easy, and not followed by any unfavourable circumstance. Ten days before the period of her expected confinement (the 19th) I was hastily summoned to see her, as she had suddenly fallen into a fit. I reached the house at nine p.m., about ten minutes after the seizure, and found her labouring under all the well-marked symptoms of apoplexy. Her breathing was laboured and stertorous, her eyes prominent and injected, the pupils widely dilated and insensible, her features swollen, the pulse slow and oppressed; she was perfectly unconscious, and a little frothy mucus, tinged with blood, issued from her mouth.

Losing as little time as possible in useless inquiries, as to whether she had complained of indisposition prior to the attack, being assured in reply that she had not, but that she had fallen as if shot,—I made the necessary arrangements for bleeding, and to my astonishment I was told by her husband and sister, that on no consideration whatever would they allow blood to be taken from her, either by bleeding, cupping, or leeching, alleging as their only reason for refusing, that they had always heard that taking blood from a person after the "*sun had gone down*" was invariably fatal. In vain were my remonstrances to overcome their superstition; the only answer I received was that I might call as early, and take as much blood from her in the morning as I pleased, but as for bleeding then, it was out of the question. I therefore took my leave, after having ordered the head to be shaved, and pounded ice to be applied, with large and repeated doses of calomel and croton oil to be given until the bowels should be freely acted upon; the head and shoulders to be raised, and the lower extremities to be kept warm, and mustard poultices to be applied to them.

20th, eight a.m. As might have been expected, I found my patient the following morning in a state of profound coma, her breathing slow and stertorous, with perfect loss of sensation and voluntary motion. Hopeless as her condition was, I thought it my duty to try the effect of a copious bleeding; accordingly, I took about twenty-five ounces of blood from her, with little or no perceptible result. The bowels had not been acted upon; the croton oil was continued in larger doses, enemata of turpentine ordered, a large blister applied between the shoulders, the catheter passed, and the opportunity taken to ascertain the state of the os uteri, which would barely admit the tip of the finger, and did not feel inclined to yield. At this time the motions of the child were vigorous and strong, so much so as to be seen by the persons around the bed.

Noon. She remained much in the same state as in the morning. Eight p.m. She was evidently sinking, pulse small and weak, surface of the body and extremities cold, bronchial tubes loaded with bloody and frothy mucus, sphincter muscles beginning to relax, the os uteri in the same condition as in the morning, the action of the fœtus strong, yet not so much so as in the morning. As it was evident that the mother must die, it appeared to me that the life of the child might possibly be saved by the Cæsarean section; it was therefore proposed to the husband, who immediately gave his consent, and requested that everything might be done to preserve the life of his offspring. Accordingly the friends were told to have everything in readiness, and to send for me as soon as they perceived the approach of death.

At eleven p.m., I was sent for, as they thought she could not survive many minutes; and just as my medical friend and myself reached the house, we were met by the husband, who told us that she had that moment breathed her last. We were also told that the movements of the child had been felt a moment or two before. No more time was lost than was necessary to assure ourselves that her dissolution was complete; and being satisfied that the vital spark had fled, I commenced the operation in the usual manner, beginning the incision about two inches above the pubes, and continuing it to the same distance above the umbilicus. The uterus being freely exposed, an incision to nearly the same extent was made through its walls, the membranes ruptured, and a full-grown female child was easily extracted by the legs, they being the parts most readily taken hold of.

A ligature was immediately placed on the cord, the child separated from the placenta, and handed to my friend. It showed no signs of life, was pale, and beautifully clean. It was immediately placed in the warm bath which had been prepared, and artificial respiration, by means of the tracheal tube, commenced; the chest and upper portion of the spinal column being alternately rubbed with a stimulating liniment.

At first our endeavours to resuscitate the child appeared unavailing, but in about seven or eight minutes from the time we began the inflation of its chest, an occasional sob took place, and in a few minutes more, the breathing and circulation were fairly established, the child ultimately recovering completely.

The placenta was removed from the uterus, and the external incision brought together by a couple of sutures, the intestines not protruding, or in any way annoying us during the operation. Permission was then obtained to examine the head.

Post-mortem twelve hours after death.—On removing the calvarium, the membranes of the brain were found most highly congested, the glandulæ pacchioni were unusually large, and the little pits on either side of the longitudinal sinus so deep, as to lead to the belief (at first sight) that the bones were diseased. On raising the brain, a very considerable coagulum of blood was observed, occupying the whole of the base of the skull, together with a small quantity of high-coloured and bloody serum. The vessel from which the extravasation had taken place could not be detected. Both the lateral ventricles were distended with bloody serum, the colour of arterial blood, but no blood was effused into the substance of the brain, which in other respects appeared firm and healthy. The uterus was found to have contracted as firmly and as equally as it would have done after a natural labour; although at the time that the sutures were put into the abdominal parietes, it had rather the appearance of a collapsed state than that of a firm contraction. The other abdominal organs were healthy. The chest was not examined.

Remarks.—The principal point of interest in this case was the preservation of the child's life, under circumstances the most unfavourable. Numerous cases are recorded, where women have died suddenly, or been killed by accidents, when in the last month of their pregnancy, and the children saved by immediate recourse being had to the Cæsarean section, but I have not met with any recorded instance where the mother had been in a state of profound coma for twenty-six or twenty-seven hours previous to her death, and where, in fact, she had been dead to every external impression, the animal functions alone being maintained chiefly through the medium of the nerves of organic life. Nothing can more clearly prove the independent existence of the child from that of the mother, except so far as the placental circulation is concerned. In a case mentioned by Dr. Blundell, where a woman, in the last month of her pregnancy, was run over, and died a few minutes afterwards, the child was removed by the Cæsarean section thirteen minutes after the mother breathed her last, and in fifteen minutes from the mother's death, artificial respiration was commenced. Dr. B. continues: "During fifteen minutes longer I continued it, ultimately resuscitating the child completely."

This case shows, that we must not be deterred from making an attempt to save the child, even fifteen or twenty minutes after the death of the mother; and, on this continent, where steamboat explosions and railway accidents are of constant occurrence, it is to be hoped, that bearing these facts in mind, the lives of some innocent beings may be saved by a timely recourse to this operation. But here, let me caution the younger and less experienced members of our profession (whose zeal and energy may occasionally run away with their better judgment) to convince themselves thoroughly of the death of the unfortunate mother, ere they commence the attempt to save the child; for, to perform this formidable operation when the woman is dying, with a chance only of saving the child, would be barbarous in the extreme, and justly deserve the eloquent reproval of my friend and former preceptor, Dr. Blundell:—"Who that has a heart of flesh in his bosom could coolly sit down in a real case to argue for the advantage to be derived to the fœtus from the performance of Cæsarean incisions before the maternal life is totally and beyond all doubt extinct? Who that has a heart of flesh in his bosom could have firmness sufficient to perform his operations under such circumstances? Who could look on the dying eyes of his patient without suffering the knife to drop from his hand? Who would like himself to be disturbed at such a moment? As long as men are surgeons, surely surgeons may continue to be men."—*Upper Canada Journal.*

POISONOUS PROPERTIES OF NICOTINE.

M. Orfila lately, at the Academy of Medicine, Paris, read an essay which had for its principal object to demonstrate—1stly, that nicotine can be as certainly distinguished as any poison derived from the animal kingdom; 2ndly, that this alkaloid can be detected in the intestinal canal, and its presence affirmed, although only a few drops of it be present in the intestinal canal; 3rdly, that its presence can be detected after its absorption into the substance of the liver and other organs. Nicotine, discovered in 1809, by the illustrious Vauquelin, was studied in 1828 by MM. Posselt and Reimann, who found it in the various species of tobacco. It was classed by them with the two other volatile natural alkalies, *conicine* and *théobromine*. Composed of hydrogen, carbon, and nitrogen, it may be represented as one equivalent of ammonia, and one of carburetted hydrogen, containing four equivalents of hydrogen and ten of carbon. It is obtained by passing the vapour of tobacco through water acidulated by sulphuric acid; the sulphate thus obtained being decomposed by a strong fixed alkali, the nicotine is thus volatilized by moderate heat. This mode of preparation points out that by inhaling the fumes of tobacco, during smoking, a portion of nicotine is introduced into the system.

Pure anhydrous nicotine is a colourless oleaginous liquid, sp. gr. 1·048, becoming yellow by keeping, and on exposure to the atmosphere changing to a brown colour, and becoming thick in consistence, by the absorption of oxygen; its acrid odour has but slight resemblance to that of tobacco, its taste has a burning pungency; it volatilizes at 250 deg. Fah., leaving a carbonaceous residue; its fumes are extremely irritating; it is inflammable, being readily ignited, burning with a white flame, and yielding abundant charcoal; it reddens turmeric; it is soluble in water, in alcohol, oils, and also in ether, which speedily separates it from a watery solution.

Nicotine combines directly with acids, heat being disengaged. Concentrated pure sulphuric acid in the cold gives a red wine colour; when heated, the liquid assumes the appearance of wine lees, and at a boiling temperature blackens, with the disengagement of sulphurous acid. Hydrochloric acid imparts to it a violet tint; nitric acid an orange tint; with stearic acid it forms a soap. Its simple salts are deliquescent, and not so easily crystallized as its double salts. Its aqueous solution is colourless, transparent, and strongly alkaline; it behaves like ammonia with many reagents: thus, it gives a white precipitate with the bichloride of mercury, acetate of lead, and chloride of tin; and with chloride of platinum, a canary yellow; the salts of zinc are precipitated white, and are redissolved by the liquid in excess; the acetate of copper is thrown down blue, and is soluble in excess; with salts of manganese it has the same action as ammonia. The following tests distinguish its aqueous solution from that of ammonia; it precipitates the chloride of gold reddish yellow, and redissolves it by excess; it precipitates chloride of cobalt blue, passing into green, and does not redissolve the precipitate as ammonia does; solution of iodine precipitates it of a yellow colour, whereas ammonia discharges the colour.

If to the chemical characters by which nicotine is thus distinguished, its action on the animal economy be added, it will be impossible to confound it with any other substance. M. Orfila related several experiments which he had performed, and which are published in the fourth edition of his *Toxicologie Générale*. These experiments show that nicotine has a directly injurious influence upon the central organs of the nervous system.

II. M. Orfila then proceeded to discuss the second proposition—viz., that nicotine can be detected in the digestive canal, when even only a few drops have been taken. The author pointed out that in the animals experimented upon, neither vomiting nor action on the bowels followed after its administration. The contents of the canal were acted upon by ether, which dissolved out the nicotine. The following method was considered by M. Orfila to be the best for the detection of nicotine in the digestive canal. The substances to be analysed are to be macerated in very diluted sulphuric acid for about twelve hours, and then to be filtered; the result will be a solution of sulphate of nicotine with some organic matters. This is to be evaporated to dryness in a sand bath; then treated with distilled water, which will dissolve the sulphate and leave the organic matters. Soda or potash is to be added, the nicotine distilled over, and the product evaporated in a sand bath to obtain the nicotine free from water. The tests before mentioned can then be applied.

III. In support of his third proposition, M. Orfila stated that the substance of the liver having been subjected to a similar examination as that to which the intestines were submitted, has been found to yield evidence of the presence of the poison. M. Orfila concluded with some observations on a recent investigation of a case of poisoning by nicotine, at Mons, in Belgium.—*Med. Gaz.*

SYNCOPE, ASPHYXIA, AND ASTHENIA.

By Lucius O'Brien, M.D.,
Professor of Medical Jurisprudence, Toronto University.

In lectures on medical jurisprudence, it becomes necessary to explain the distinctive meaning of the terms syncope, asphyxia, and asthenia, with the particular train or series of action, or loss of action, connected with each; but although each of them has occasionally received a full share of investigation, I have not yet met with any work in which they are treated so as to give the student those clear and distinct ideas in regard to them, which he ought to possess, arising from the loose and vague manner in which these terms have been applied. To supply this want is the object of the present sketch.

As the study of medical jurisprudence is not confined to the medical practitioner, but has deservedly become an object of deep interest to the profession of the law also, I shall as far as possible employ the plainest terms, and, avoiding unnecessary speculation, confine myself to a simple statement of facts.

Syncope, asphyxia, and asthenia, are three states or conditions arising from, or connected with, a cessation of the action of the heart, from various causes.

I. Syncope, synonymous with *fainting*, arises from hæmorrhage or loss of blood; rupture of the heart; the sudden or severe action of purgatives, generally in a weakened state of the system; the sudden assumption of the erect position; fright, or other mental emotion; in short, from any cause which prevents the heart from sending the arterial blood to the brain, not dependent on obstruction to the pulmonary circulation.

In death from syncope, the heart is found *empty*, or nearly so, and *contracted*, and the bloodvessels in general contain but little blood. Here the immediate or proximate cause of death is the non-supply of arterial blood to the brain and nervous centres, the heart primarily ceasing to act from the supply of blood to *both sides* being deficient. The question naturally arises—what causes this deficient supply of blood?

II. Asphyxia, or preferably Apnœa, synonymous with *suffocation*, arises from any cause which impedes the circulation of the blood through the lungs, thereby producing engorgement of the pulmonary arteries and the right side of the heart. Consequent on this we have distension of the venæ cavæ, with venous engorgement of the liver, spleen, head, &c.

The causes, being *anything* which impedes the circulation through the lungs, embrace—1st. Cessation of the action of the muscles of respiration from loss of nervous influence, as from injury to the upper part of the spinal marrow, injury or division of the phrenic nerves, severe cold, debility, as in new-born infants, mechanical restraint, as pressure on the thorax or abdomen, pressure on the lungs by the admission of air into the cavities of the pleura, or the upper pressure of the abdominal viscera through a wound of the diaphragm, spasm, as in tetanus. 2nd. Cessation of the vital action of the lungs themselves from loss of vital influence, as from injury or division of the eighth pair of nerves. 3rd. Mechanical exclusion of the air from the lungs, as in hanging, drowning, or other mechanical means of suffocation, as by a foreign body in the trachea, &c. 4th. Want of respirable air, as in extreme rarefaction of the atmosphere, as on very high mountains, or the presence of an undue proportion of nitrogen, nitric oxide, or hydrogen gases. 5th. The presence of deleterious or poisonous gases, as carbonic acid gas, carbonic oxide gas, carburetted hydrogen gas, sulphuretted hydrogen gas, arseniuretted hydrogen gas, hydrocyanic acid (gaseous), chlorine, sulphurous acid gas, ammonia, &c. 6th. Diseases of the lungs themselves, rendering them impermeable by the air, as hepatization, œdema, emphysema, apoplexy (pulmonary), &c., which act mechanically.

The proximate cause of death in asphyxia is the cessation of the nervous or vital power of the brain owing to a want of arterialized blood; and the steps of the process are—1st. Arrest of the transmission of the blood through the capillary vessels of the lungs. 2nd. Accumulation of dark blood in the pulmonary arteries and right side of the heart, and consequent congestion in the venæ cavæ, with venous engorgement of the liver, spleen, head, &c. 3rd. Arrest of the supply of arterialized blood to the left side of the heart, and consequently want of stimulus to its due action. 4th. Want of arterial blood in the brain and nervous centres, causing cessation of vital action.

III. Asthenia.—We accept this term to express direct paralysis or total loss of innervation of the heart, *both sides of it being affected*, its motive powers being destroyed, irrespective of the blood itself as to the quantity, and, as far as we really know, as to the quality. The causes, then, of asthenia are everything which primarily destroys the vital action of the brain and nervous centres, embracing those causes which form the first class in Guy's tabular arrangement—viz., "lightning, severe blows on the head, severe constitutional shocks, strong mental emotions," to which we may add certain poisons.

In asthenia we find the heart flaccid, containing blood, more or less, in all its cavities, and the bloodvessels, both systemic and pulmonic, also containing more or less blood, arising from the sudden arrest of vitality.

It would be quite foreign to my purpose to enter into any review of the actual or possible combination of these states, but I cannot conclude without observing that what is called syncopal asphyxia, or idiopathic asphyxia, is not asphyxia at all. It is either syncope or asthenia.—*Upper Canada Jour.*

DUBLIN: WEDNESDAY, JULY 2, 1851.

MEDICAL CHARITIES' BILL.

The following is a brief report of the debate on this measure which took place on Wednesday last. A more lengthened one has been published in some of the papers, but so full of absurd blunders that we cannot rely on it. The truth is, that no reports published in the London papers of debates on Irish affairs can be trusted, except the question at issue involves the consideration of British interests. It appears that there is no formidable opposition to the bill in the Commons, and that it will probably pass there with more or less alteration. It appears, also, from the debate, that many dispensaries, several fever hospitals, and some infirmaries, will be extinguished, and that others will be moved from their present positions; but it is assumed that more permanent and less precarious provision will be made for the remaining institutions in future. We have all along been compelled to handle this subject with great reserve, believing that its advantages, whatever they may be, are not unalloyed by serious disadvantages; but we have not failed to bring before our readers all the points of importance connected with it which require particular attention. Now it is our business to remind our brethren that the period has arrived for a most careful scrutiny of the bill, with a view to its amendment in any particular provision which may appear dangerous; not, however, by any attempt at opposition, but by appeal to Sir W. Somerville, who will doubtless adopt any reasonable suggestion:—

HOUSE OF COMMONS—WEDNESDAY, JUNE 25.

MEDICAL CHARITIES (IRELAND) BILL.

The house went into committee on this bill.

On the question that the preamble be postponed,

Lord Naas objected to the principle of rating contained in the bill. It was the first occasion on which rates had been raised after the manner of the poor-rate for the support of charitable institutions, and he was afraid that this instance would be used as a precedent for future purposes.

Sir William Somerville explained that the object of the bill was to distribute the expenses of these charities, which had formerly been borne by the occupiers alone, over all classes equally, and that was the reason why this system of rating had been pursued.

Mr. G. A. Hamilton said he was sure it was by no means the intention of his noble friend to require from the right hon. baronet opposite any very detailed estimate, or to hold him strictly to any statement he might then make; but considering the pressure of local taxation upon Ireland, the committee had a right to expect that such information should be given on the part of the government as would enable them to judge fairly of the probable cost of the proposed system of medical relief. Upon the whole, he thought the statement of the right hon. baronet a fair one. He understood him to state that there being now about 668 dispensaries, he proposed reducing them to 460, and that he calculated the expense at £44,000 a year; and that there being now 104 hospitals and infirmaries, he proposed reducing them to 74, and calculated the expense at £53,655. That would make the cost of medical charities in Ireland about £100,000 a year. He (Mr. Hamilton) would be well satisfied if he could feel assured that this estimate could be relied on—if he could feel assured that the rate to be levied for medical charities in Ireland would not exceed 2*d.* or 2½*d.* in the pound, and if provision could be made in the bill, that the rates levied should not exceed that amount, he would say at once that the measure would be very advantageous for Ireland. He would now propose the first amendment of which he had given notice. The committee would observe that two commissioners were to be added to the poor-law board, that these commissioners were given the power not only of administering the system of relief, but of determining the qualifications of the medical officers of all institutions. It was therefore most important that the commissioners should possess, as far as possible, the confidence of the profession. The bill provided that one of these commissioners should possess the double qualification of physician and surgeon. He (Mr. Hamilton) was far from thinking that it would not be desirable, in selecting the medical commissioner, that government should select a gentleman possessing the double qualification, but he did not think it desirable that they should be restricted by law. The most eminent men in the profession in Ireland, at the present moment—Dr. Stokes, Sir Henry Marsh, Dr. Graves—possessed only medical qualifications as physicians, and other very eminent men were pure surgeons. It might happen that the most eligible person in whom the public and both branches of the profession would have the greatest confidence, might be either a pure physician or a pure surgeon, and it would not be desirable that for want of the double qualification such a person should be disqualified; he therefore proposed to substitute "or" for "and."

Sir Wm. Somerville would not object to the amendment.

After some desultory discussion, the clause, with some verbal amendments, was agreed to.

On clause 2 being proposed,

Sir R. Ferguson moved the omission of the words "or hos-

pital district or districts," for the purpose of not conferring any other power on the commissioners over hospitals than that of inspection.

Mr. Reynolds opposed the amendment. In consequence of the want of inspection in county and workhouse hospitals, thousands of people had died from wilful neglect and need of proper medical advice and treatment.

Sir W. Somerville hoped the house would not agree to the proposition of the hon. baronet; for great as the abuses were in connexion with hospitals and infirmaries in Ireland, they would be increased if those institutions were not included within the operations of the bill.

Sir D. Norreys opposed the amendment, and hoped the bill would be given up altogether if it were carried.

Colonel Dunne said the bill was only an experiment, and he thought it would be best to try it upon dispensaries first, and if it were found to work well, then its provisions could be extended to hospitals.

Lord Bernard did not think it would be advisable to introduce the amendment into the bill now.

Mr. French was not disposed to support the amendment.

Mr. Vesey recommended the government to adopt the plan of the hon. member for Londonderry, and they would get rid of all the other amendments that were to be proposed in the bill.

Mr. S. Crawford expressed a hope that the amendment would not be carried, as he felt all medical charities ought to be placed on the same footing, and under the same control.

Mr. O'Flaherty also called upon the committee to reject the amendment, and allow all the medical charities to rest upon one general fund. If, however, the bill was not to be adopted in its integrity, he would much rather wait for another year before legislating on the subject at all.

Mr. Clements supported the amendment, adding that it could be easily recalled next session if it did not succeed.

After a few words from Mr. Conolly and Sir W. Somerville,

Lord Naas said he should be the first person to support the bill if he thought it would do Ireland any good; but he had heard nothing proved against the existing management of the hospitals, and in the absence of any such proof he could see no reason for changing the system.

Colonel Rawdon implored the committee not to allow the bill to be defeated, as it was calculated to confer a great and lasting boon upon Ireland.

Mr. Hamilton—If they were to divide now, he must occupy the time of the committee for a few moments. He agreed fully with his noble friend near him in what he had stated with regard to the medical officers of infirmaries in Ireland. No body of men stood higher in public estimation, and the state of the infirmaries generally reflected the greatest credit upon their management and professional attainments. As he understood the amendment of his honourable friend, it referred only to hospitals; the clause gave the power of dividing the country into dispensary and hospital districts; if the word "hospitals" were struck out as was proposed, the commissioners would have no power to make hospital districts. But infirmaries had no districts under the present law; therefore, as he thought, the question of infirmaries was not touched by the clause, and the question was confined to the expediency of extending the bill to hospitals. If there were time, he could show that nearly all the evils incident to dispensaries were equally applicable to hospitals. He saw no reason for postponing the question of hospitals to another session. Nothing could be more objectionable than uncertainty with regard to legislation in such matters; and therefore, though differing from many of his friends about him, he felt bound to support the government in retaining the word "hospital" districts.

After a few words of explanation from Sir W. Somerville and Colonel Dunne, the committee divided, when there appeared—

For the amendment	...	...	...	24
Against it	...	...	...	85
Majority	...	...	...	—61

The amendment was consequently lost.

On the motion of Mr. Clements, the Chairman was instructed to report progress, and the house having resumed, he did so accordingly.

The following version we copy from the *Times*:—

Lord Naas was extremely desirous to hear from his right hon. friend some explicit statement of what the contemplated addition to the taxation would be; what extension of dispensaries and hospitals would take place; what new medical officers would be required; and generally, what the practical manner and effect of the change would be.

Sir W. Somerville said that the amount expended for medical charities in Ireland under the existing system might be taken at from £120,000 to 126,000 yearly, but the estimated expense of the new system would be considerably less. The number of dispensaries in Ireland was about 670, but his opinion was that if those institutions were properly managed, and if districts were carefully formed, the number might be considerably reduced. Indeed, he believed that about 460 dispensaries, if they were properly distributed over the country, would be sufficient. He calculated the average expense of each dispensary at £95 a year, so that a sum of £44,175 would be required for the support of dispensaries. He believed that, by adopting the system of district hospitals, a very large number of the infirmaries and fever hospitals might be dispensed with; for the existing plan of having the fever hospitals separate from the infirmaries rendered it necessary to keep up a very large number of these institutions. He considered that if districts were properly formed throughout the whole of Ireland, about 74 district hospitals or infirmaries, containing 68 beds each, would be quite sufficient. He understood that the average number of beds provided in the infirmaries now established was about 50 each, and by the plan he proposed, although the number of hospitals would be reduced, the number of beds would be increased. The increase of the number of beds under this bill would be about 1000. The expense of the hospitals and infirmaries was calculated at £53,655, so that the total expenditure under this measure would be about £97,830 a year.

We find that Mr. O'Flaherty, the member for Galway, has carried an amendment which will exclude from the much-coveted commissionership all candidates under ten years' standing: which of them it "hits" we cannot tell. The same gentleman proposes that the commissioner should be allowed to practise while engaged in the discharge of his public duties, but we cannot discover how his truly Irish proposal fared, neither can we well guess for whose use and behoof these bits of comfortable legislation are propounded. As for allowing the proposed commissioner to practise his profession while filling such an office it is monstrous: such an arrangement would establish a frightful system of corruption, and legalize a regular practice of bribery by means of mock consultations. If there be one point more than another to which Sir W. Somerville is pledged, it is to the defeat of this job, and the prevention of the scandalous practices which must follow its perpetration.

PHARMACY BILL.

A Bill for regulating the qualifications of Pharmaceutical Chemists and the Practice of Pharmacy, has been introduced by Mr. Jacob Bell, the member for St. Alban's, and editor of the *Pharmaceutical Journal*. The following copy of the Preamble will explain its object:—

Whereas it is expedient for the safety of the public that persons exercising the business or calling of pharmaceutical chemists, chemists and druggists, or dispensing chemists, in Great Britain, should possess a competent practical knowledge of pharmaceutical and general chemistry, and with other branches of useful knowledge: And whereas certain persons desirous of advancing chemistry and pharmacy, and of promoting an uniform system of education of those who should practise the same, formed themselves into a society called "The Pharmaceutical Society of Great Britain," which said society was on the eighteenth day of February, one thousand eight hundred and forty-three, incorporated by Royal Charter, whereby it was provided that the said society should consist of members who should be chemists and druggists who were or had been established on their own account at the date of the said charter, or who should have been examined in such manner as the council of the said society should deem proper, or who should have been certified to be duly qualified for admission, or who should be persons elected as superintendents by the council of the said society: And whereas it is expedient to prevent ignorant and incompetent

persons exercising the business or calling of pharmaceutical chemists, chemists and druggists, or dispensing chemists, in Great Britain, and to that end it is desirable that all persons before exercising the said business or calling, should be duly examined as to their skill and knowledge by competent persons, and that a register should be kept by some legally authorized officer, of all persons engaged in the said business or calling: And whereas for the purposes aforesaid, and for extending the benefits which have already resulted from the said Charter of Incorporation, it is desirable that additional powers should be granted for regulating the qualifications of persons who may carry on the business of pharmaceutical chemists, chemists and druggists, or dispensing chemists, and for other purposes connected with the practice of pharmacy: Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present parliament assembled, and by the authority of the same, &c. &c.

This we consider a measure of great value and importance; it is in fact a necessary consequence of the abandonment of the pharmaceutical department by the apothecaries' companies, and their insane notions respecting their claims to be considered licensing medical bodies. Of the extension of the act to Ireland in process of time, should it become law in England, there can be little doubt; and then shall we have realized the views of the late Mr. Carmichael, and those who supported him some ten years ago.

MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

The Treasurer has received the following sums:—

Dr. Geary, Limerick	£1	0	0

C. Benson, Secretary.

OPIUM-EATING IN ENGLAND.

Will you allow an old subscriber to say a few words on the practice of opium-taking—a practice which, I fear, is much on the increase in the rural districts of this country. The subject is highly important to the public, and not uninteresting to the profession at large. At the same time, there is little or no information respecting it to be met with in medical works. The question I wish to put is this—Is it possible to reform a person who has been long addicted to the practice of taking opium? We all know the injurious effects its long-continued use produces both on body and mind; but it is only the unfortunate victims themselves who can depict the miserable depression, the indescribable uneasiness, they experience when deprived of the accustomed dose. Since the crusade of the teetotallers against spirit-drinking, there is great reason to believe that the practice of taking opium is on the increase; and when one of the first of our physicians describes it as a virtuous and comparatively harmless species of excitement, compared with gin-drinking, I cannot but think he treats it with undue lenity, and may unintentionally contribute to the extension of the vice. For those unfortunate creatures who daily resort to this baneful drug as a cheap species of intoxication, I have but little sympathy or commiseration. Their weakness entails a severe punishment even in this world. But there are others, especially among the middle classes of society, who resort to the use of opium under the pressure of severe mental distress; and although nor poppy nor mandragora can

> "Pluck from the memory a rooted sorrow,
> Or rase the written troubles of the brain,"

still there are many cases in which morphia, or some other sweet oblivious antidote, by procuring sleep, preserves the sufferer from painful or heart-rending recollections. When relief is obtained by such means, the practice soon becomes habitual. What was at first a moral solace is now converted into a physical necessity; while Time, the great mediciner, which sooner or later softens the pangs of every mourner, only serves to strengthen the chains of that habit, into which his sufferings have betrayed him. It is for an unfortunate being of this description that I now bespeak your sympathy, and respectfully request the advice of my more experienced brethren. Some two years ago, after a severe domestic trial, my friend was induced to resort to morphia as a means of procuring sleep; but though the violence of his grief has long since subsided into a tender melancholy, he finds himself unable to throw off the habit he has so unwittingly contracted. Deprived of the accustomed dose, which I should premise is not a very large one, he describes himself as "irritable, dejected, prostrate in body and mind, and utterly incapable of discharging the ordinary duties and business of life." What can be done in such a case? Should I advise him to leave it off totally and at once, and trust to time and nature for relief? Or do you recommend a gradual diminution of the dose? Is there no other stimulant less injurious in its effects, yet still capable of preventing that collapse of the system which assails every victim who wishes to reform? In short, what is the best course to follow for an opium-taker who wishes to desist from the practice, and who is otherwise in good health? Are we to consider entire abstinence impossible, when the practice has been indulged in upwards of two years? Coleridge used to assert that he could leave off when he chose, and I have heard many others say the same; but I never knew but one who permanently succeeded in his efforts at reform. If the experience of any of your learned correspondents should enable them to throw a little light on this subject, I should feel greatly obliged by the communication, and it would prove, I think, generally acceptable to your readers. That opium-taking is on the increase, any one may convince himself by making inquiries of the druggists. In the county in which I reside it is well known their chief profit consists in the retail sale of opium. In conclusion, permit me to observe, notwithstanding the dreadful effects on the system at large which opium-taking commonly produces, that I know many old people who have taken it for years, with little apparent injury to their health. Continued observation has also forced on me another idea, which I promulgate with less confidence—namely, that the habitual use of opiates is in some way or other a powerful prophylactic against phthisis and diseases of an inflammatory nature.—*Letter in Lancet.*

ADULTERATION OF TEA.

It appears that the "glaze" on the surface of certain kinds of green tea is given to it by the manufacturer, not with a view to adulteration, but for the purpose of suiting his foreign customers. This glaze is composed of a mixture of Prussian blue, turmeric, and fibrous gypsum; a small portion of which is sufficient to give the requisite glaze to a large quantity of tea. There is, however, an extensive adulteration of tea practised in China, not by the desire of the manufacturer, but to meet the price offered by the importers of the tea into England. Some samples of this tea examined by Mr. Warington, were found to consist of powdered tea, sand, and dirt, agglutinated together by means of gum; the black being coloured with plumbago, and the green with the facing above mentioned. On analysis, these teas were found to give from 35 to 45 per cent. of ashes on incineration, whilst good tea did not give more than 5 per cent. of ash, the excess in the adulterated specimens being composed of sand, dirt, and other extraneous matter. Upwards of 750,000 pounds of this tea have been imported into this country within eighteen months. The adulteration may be detected from the circumstance, that on the addition of boiling water, there is no opening or unfolding of the leaf, as in good tea, the fact being that there is no leaf to unfold. The Chinese call this Lie-tea, and prepare it only to suit the wishes of the importers. Attempts were made to pass these teas at the Custom House as manufactured goods, paying an *ad valorem* duty of 10 per cent., instead of the usual rate of 2*s.* 1*d.* per pound. The name "gum-and-dust" is given by the trade to the tea with which this fraudulent article has been mixed. It would appear that the difference between green and black tea, as far as regards their physical and chemical condition, arises from the fact that the latter in its preparation is made to undergo a species of fermentation and oxidation previous to being roasted.—*Mr. Warington in Phar. Jour.*

THE UNIVERSITY OF ST. ANDREW'S AND HOMŒOPATHY.

THE following correspondence has taken place between Professor Day of St. Andrew's and Dr. Robert Douglas Hale:

"St. Giles's-street, Norwich, June 12, 1851.

DEAR SIR,—It would have been more courteous to have waited for a reply from me before sending your communication to the *Lancet*. I shall therefore simply state, that it was not my business to declare myself a homœopathist, and that I think your expression of 'grossest deception,' is wholly inapplicable either to me or to any one who, under such circumstances, practises such reserve as I did. The obvious aim I had in view in replying to the questions put at my examination, was to prove that my knowledge of medicine was such as to entitle me to the certificate of competency to practise in the usual mode followed, and that it was not from ignorance of the old system that I had conscientiously adopted the new.

I cannot imagine that you, or any right-minded man who considers the present state of medicine, and of medical parties in these realms, would, after due consideration, apply the term you have used, to a reserve so necessary as that I practised, in not putting forward my therapeutical views.

For the censure or praise of a bigoted and prejudiced periodical I care but little, but I do regret that my conduct should for a moment appear in a light it ill deserves, in the eyes of the enlightened professor of medicine in the university from which I have had the honour of receiving my degree.—I remain, dear sir, very faithfully yours,

ROBERT DOUGLAS HALE.

To George Day, Esq., M.D."

"St. Andrew's, June 14, 1851.

DEAR SIR,—I regret that your answer to my note is of so unsatisfactory a nature. While I beg to assure you that I have no wish to apply the term 'grossest deception' to your conduct in a personally offensive view, I must still express my opinion that no honest homœopath, conscious that the examiners trusted to his honour 'to specify the mode of treatment he is in the habit of adopting, and the doses of the medicines which he prescribes,' could have obtained his degree at our last examination.—I am, dear sir, faithfully yours,

GEORGE E. DAY.

To Dr. Robert Douglas Hale."

Any comment on the letter of Dr. Hale is obviously unnecessary. It affords a great pleasure to be enabled to state that the University of St. Andrew's are taking active measures in this matter, with the view of vindicating the character of the university. The conduct of Professor Day is entitled to all praise, and offers an example which might be followed with advantage by the principals of other universities and colleges which are much disposed to boast of their *orthodox* respectability.—*Lancet.*

As much blame has been imputed to the professors of the University of Edinburgh for their alleged apathy in regard to the homœopathic perversion of a colleague, we think it right to state that the medical faculty have done all that was in their power. Several years ago, when it first became known that Dr. Henderson was treating acute inflammatory affections by the administration of globules, in the clinical wards of the Royal Infirmary, the medical faculty having in vain remonstrated with him, intimated to the managers of the hospital that they did not wish he should any longer act as one of the professors of clinical medicine, and he was dismissed accordingly. As to the professorship of general pathology, the medical faculty have no power in the way of appointment or dismissal; but we have no doubt that if it ever came to their knowledge that Dr. Henderson was making his lectures from this chair the vehicle of homœopathic doctrines, they would petition the patrons for his removal. The testimony of students who have attended this course, assures us there has hitherto been no ground for any such complaint; and so long as this is the case, we do not see how the medical faculty can take cognizance of the principles upon which their colleague chooses to conduct his private practice.—*Edin. Monthly Jr.*

In Dr. (?) Bell's letter I see he signs himself M.R.C.S.I., &c., but not M.D. Now, he has *Dr.* on his cards and on his door. Perhaps he may think it right to inform some who doubt the fact, whether he is an M.D., and of what university? If he be, it is strange that in his letters, and also in his return to the *Directory*, he has omitted to notify the same. —*Letter in Lancet.*

THE PRESS AND THE QUACKS.

IT is generally considered in this country that the advertising quacks exercise a great influence over a portion of the periodical press, by their constant advertising; there can be no doubt but that the editors who admit these polluting announcements into their journals, become accomplices with the quacks in their barefaced pretensions. But the French charlatans, as we learn by the *Presse Médicale de Bruxelles*, distance the English completely respecting the hold they have taken upon the periodical press. This will become apparent when we state, that the Parisian quack who sells an anti-syphilitic medicine, which is very appropriately called "*Rob*," is co-proprietor of such papers as *Le Siècle*, *Le Constitutionel*, *Le Corsaire*, and even *L'Abeille Médicale*.

HALF-YEARLY ABSTRACT OF THE MEDICAL SCIENCES.

Edited by W. H. RANKING, M.D., Cantab.,
Physician to the Norfolk and Norwich Hospital.

"This is one of the most valuable medical publications of the times."—*North Western Surgical Journal.*

*** For the accommodation of new subscribers, the Entire Series of Twelve Volumes, giving the most comprehensive view of the Progress of Medical Science during the years 1844 to 1851, may be had at the reduced price of £3 3*s.*

London: John Churchill, Princes-street, Soho.

BRAITHWAITE'S RETROSPECT OF MEDICINE.

Just published, price 6*s.*, cloth, Vol. XXIII.—January to June, 1851,

GIVING a careful Analysis of the most Practical Papers, Lectures, and Transactions of Societies, published in all the Medical Journals within the last Six Months. Appended to which is an Alphabetical List of Diseases; with the most recent Suggestions of Treatment.

Edited by W. BRAITHWAITE,
Lecturer on Obstetric Medicine in the Leeds School of Medicine, &c.

London: Simpkin, Marshall, and Co.: Edinburgh: Oliver and Boyd. Dublin: Hodges and Smith.

THE ROYAL MEDICAL HALL,
64, DAME-STREET, DUBLIN.

☞ *Change of Proprietorship.*

BEWLEY, OWEN, AND CO., APOTHECARIES,
(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS,

will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT

embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick-room and nursery.

*** GENUINE COD-LIVER OIL,

of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

DISPENSING OF MEDICINE.

G. OLDHAM AND CO.,

PHARMACEUTICAL CHEMISTS, AND APOTHECARIES,
From BEWLEY and EVANS',
No. 107, GRAFTON-STREET, DUBLIN,
(Corner of Suffolk-street),

BEG to return their grateful acknowledgments to the Medical Profession for the support they have hitherto received, and which they will regard as a fresh motive for exertion. Abstaining altogether from visiting as Apothecaries, except for the application of Leeches, Cupping, and such operations as are performed under medical advice, they will continue to devote themselves exclusively to the duties devolving on the pure Pharmacien.

Having had much experience in Practical Pharmacy, and being resolved to spare neither trouble nor expense in order to have every article of superior quality, they hope by attention, "carefulness," punctuality, and moderation of charges, to commend themselves to the approbation of those who may entrust them with their commands.

☞ *G. O. and Co. invite attention to their present stock of Surgical Instruments, all of which are manufactured on the most modern and improved principles.*

ROYAL COLLEGE OF SURGEONS.

THE Professors of Anatomy will appoint a Demonstrator on MONDAY, July 14th. Candidates for the office should transmit their proofs of qualification, one week at least before the day of election, under cover to Mr. BOYLAN, the Registrar at the College.

THE REVERSED AND DOUBLE-ACTIONED PATENT TRUSS.

Invented by FRANCIS L'ESTRANGE, Esq., F.R.C.S.I.

WILLIAM DUFF, of 37, Molesworth-street, Dublin, calls the attention of the medical profession and the public to this Truss. He can state with confidence it is the only instrument constructed on scientific principles, having for its object the Radical Cure of Rupture. It acts not merely as a palliative, but will produce a radical cure, as is attested by numerous certificates.

W. D. is the only Manufacturer of the Instrument. The trade and public institutions will be liberally dealt with.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the city of Dublin.
London: John Churchill, 46, Princes-street, Soho.

ON CATARACT OR OPACITIES OF THE CRYSTALLINE LENS.

By ARTHUR JACOB, M.D., F.R.C.S.,

Professor of Anatomy and Physiology in the Royal College of Surgeons in Ireland, and Surgeon to the City of Dublin Hospital.

IT is scarcely necessary to state that cataract is the name given to that disease of the eye in which blindness is caused by loss of transparency in the crystalline lens; and under that name, therefore, all opacities whatever of that part should be considered. Certain appearances, generally accompanied by defective vision, have been denominated glaucoma; but if it is meant to attribute these appearances and the defective vision which accompanies it to any loss of transparency in the crystalline lens, the term should not be used, the disease being in that case only a form of cataract. The application of two different names to the same disease is calculated to create confusion. I am not here, however, going to inquire what the disease called glaucoma is, I only want to have it settled that it is not cataract, or that if it is, it should be so called.

Notwithstanding all that has been already written on the subject, I think it is necessary to preface what I have to say respecting changes in structure of the crystalline lens by a description of that part in its natural and healthy state. It is, as every one knows, what is called a double-convex lens, or rather like two plano-convex lenses united at their plane surfaces; for its anterior surface is much less curved than its posterior: if it was not, we should have it touching the iris, and perhaps interfering with the contractions of the pupil. Its minor axis measures about seven-fortieths of an inch; or in other words, it is seven-fortieths of an inch thick; being about one half the length of its major axis or breadth. If we consider the surfaces of the lens to be spherical, we may say that the posterior is a segment of a smaller sphere than the anterior; or in other words, it is much more convex: the surfaces are not, however, strictly speaking, spherical, but perhaps spheroidical, or even elliptical or hyperbolical. These curvatures, it must also be recollected, are very different at different periods of life. In youth, perhaps we may say to the period of puberty, they are more curved, but from this period to forty-five or fifty, they remain stationary, when they become less so; in fact, the lens in children is much thicker or more convex, while in old persons it becomes less convex, thinner, and flatter. The consideration of these changes are of great importance in a practical point of view, because although the greater convexity in early life does not seem to render the eye myopic, the flattening in advanced life causes it to become presbyopic. The greatest difference also often exists in different individuals in this respect, causing short or long sight throughout life, and even in the same individual the lenses appear to be frequently unequal, causing serious imperfection of vision. In incipient cataract, the curvatures of the lens often alter, sometimes causing persons to lay aside their spectacles, and sometimes to change them for others of shorter focus. I am of course aware that the differences above alluded to may be attributed to other causes, but the undisputed fact that the lens becomes much flatter as we advance in life, and that at the same time the eye becomes presbyopic, appears conclusive as to the cause and effect.

With a view to determine the causes of the changes which take place in vision from age or alteration in structure, it is necessary to consider the refractive power of the crystalline lens. The refractive power of the capsule has not been ascertained, but it is probably greater than any other of the transparent parts, although from its being so very thin it has little effect in altering the direction of the rays of light. The body of the lens is not of equal density throughout, being scarcely denser than water at the surface, but increases gradually in density to the centre, so that probably the rays do not pass through it in straight lines, but more or less curved. The mean refractive index is, however, held to be 1.384, and its principal focal length in air about one-third of an inch, perhaps its power may therefore be considered half way between water and glass. The density, and consequently the refractive power of the lens, becomes greater in advanced life, and for anything

we know to the contrary, there may be some difference in this respect, as well as in the curvatures of the surface, in different individuals; so that, whether from this cause, or from some peculiarity in organization, or from defect of adjustment in the size or place of the pupil, very serious imperfections of vision frequently occur, and are often confounded with incipient cataract or imperfect amaurosis. I every day meet with cases in which one eye is almost useless from some of these causes or a combination of them, and in which I know there is no loss of transparency of the lens or diminution in sensibility of the retina. In such cases relief may sometimes be afforded, especially in near-sighted persons, by the use of glasses calculated to compensate for or neutralise the defect; or perhaps we may effect some improvement by influencing the state of the pupil by external applications. Imperfections of vision from the causes here noticed sometimes occur at the commencement of the period when the lens begins to flatten, and disappear in a year or two when the change in form arrives at its utmost extent.

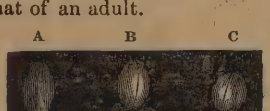
Having premised so much with respect to the form and refractive power of the lens, it may not be superfluous to repeat what I have already stated respecting this part of the eye in the Cyclopædia of Anatomy;* being convinced that a correct knowledge of the structure of any part is the first requisite towards a correct comprehension of the changes it undergoes from disease, and that no brief or meagre description is sufficient to convey that knowledge: it is as follows:—

It has been already stated that there is a double convex lens within the sphere of the eye, at a short distance behind the external lens or cornea. This is the crystalline lens or crystalline humour, which gives additional convergence to the rays of light transmitted through the pupil. It is placed in a depression, formed for its reception on the anterior, compressed, or truncated portion of the vitreous humour, where that body approaches the back of the iris, and constitutes part of the boundaries of the posterior chamber of the aqueous humour. In this depression it adheres firmly to the hyaloid membrane, and from the vessels of that structure derives its nutriment.

This double convex lens does not present the same curvature on both surfaces, the anterior being less curved than the posterior, in the ratio of about 4 to 3. Attempts have been made to determine with accuracy the nature of these curvatures, first by Petit, and subsequently by Wintringham, Chossat, and others. The results of the numerous experiments of Petit lead to the conclusion, that the anterior curvature is that of a portion of a sphere from six to seven lines and a half in diameter, the posterior that of a sphere of from five to six lines and a quarter. From the same source it appears that the diameter is from four lines to four lines and a half, the axis or thickness about two lines, and the weight three or four grains. I am, however, inclined to agree with the observation of Porterfield, that, "as it is scarce possible to measure the crystalline and the other parts of the eye with that exactness that may be depended on, all nice calculations founded on such measures must be fallacious and uncertain, and therefore should, for the most part, be looked on rather as illustrations than strict demonstrations of the points in question." The method by which Petit arrived at these results must render them of doubtful value, the curvatures having been determined by the application of brass plates cut to the requisite form. The results of Chossat's experiments, conducted with great care, and with the assistance of the megascope, are thus stated by Mr. Lloyd in his treatise on Optics:—"This author has found that the cornea of the eye of the ox is an ellipsoid of revolution round the greater axis, this axis being inclined inwards about 10 deg. The ratio of the major axis to the distance between the foci in the generating ellipse he found to be 1.3; and this agreeing very nearly with 1.337, the index of refraction of the aqueous humour, it follows that parallel rays will be refracted to a focus, by the surface of this humour, with mathematical accuracy. The same author found likewise that the two surfaces of the crystalline lens are *ellipsoids* of revolution round the *lesser* axis; and it is somewhat remarkable that the axes of these surfaces do not coincide in direction either with each other, or with the axis of the cornea, these axes being both inclined *outwards*, and containing with each other, in the horizontal section in which they lie, an angle of about 5 deg." It must not be forgotten that these observations apply to the crystalline of the ox, not to that of man, and also that, as Chossat himself admits, the evaporation of the fluid part of the lens, or the absorption or imbibition of the water in which it is immersed, may materially alter the curvature. I cannot myself believe it possible to separate a fresh lens in its capsule perfectly from the hyaloid membrane without injuring its structure, and endangering an alteration in its form. Haller states that Kepler considered the anterior convexity to approach to a spheroid, and the posterior to a hyperbolic cone. Wintringham states the results of his inquiries as to this matter as follows:—"In order to take the dimensions of the eye of an ox, I placed it on a horizontal board and applied three moveable silks, which were kept extended by small plummets, so as to be exact tangents to the arch of the cornea, as well at each canthus, as at the vertex; then applying a very exactly divided scale, I found that the cord of the cornea was equal to 1.05 of an inch, the versed sine of this cord to be 0.29, and consequently the radius of the cornea was equal to 0.620215 of an inch. I then carefully took off the cornea, and replaced the eye as before, and found, by applying one of the threads as a tangent to the vertex of the crystalline, that the distance between this and the vertex of the cornea was 0.355 of an inch. Afterwards I took the crystalline out without injuring its figure, or displacing the capsula, and then applying the threads to each surface of this humour, as was done before to the arch of the cornea, I found that the cord of the crystalline was 0.74 of an inch, and its versed sine, with respect to the anterior surface, to be 0.189 of an inch, and consequently the radius of this surface was 0.45665 of the same. In like manner the versed sine to the same cord, with respect to the posterior surface of the crystalline, I found to be equal to 0.38845 of an inch. Lastly, I found the axis of the crystalline and that of the whole eye from the cornea to the retina to be 0.574, 2.21 respectively. Whatever doubts may be entertained respecting the accuracy of the measurements of the lens, there can be none that the form is different at different periods of life, in the human subject. It also appears to differ in different individuals at the same period of life, and probably the curvature is not the same in both eyes. In other animals the difference in form is most remarkable. In the human fœtus, even up to the ninth month, it is almost spherical. Petit states that he found the anterior curvature in a fœtus of seven months, a portion of a sphere of three lines diameter, and the posterior of two and a half, and the same in a new-born infant. In an infant eight days old, the anterior convexity was a portion of a sphere of four lines, and the posterior of three. All anatomists concur in considering the lens to approach more to a sphere at this period. In childhood the curvatures still continue

* For the article Eye in the Cyclopædia of Anatomy here alluded to, I venture to take this opportunity of claiming a fair consideration at the risk of being charged with undue partiality towards it, because it was prepared by myself. Articles in encyclopædias are frequently looked upon as mere compilations, and are therefore seldom referred to as depositories of original information, but many of those of the Cyclopædia of Anatomy were of the latter description. Upon the article on Anatomy of the Eye, no expense was spared by the publishers, and I can safely say that no trouble was spared by me. I therefore can refer those who attach value to information derived from this source to it with confidence.

much greater than in advanced life; from ten to twenty probably decrease, and from that period to forty, forty-five, or fifty, remain stationary, when they become much less; being, according to the tables of Petit, portions of spheres from seven to even twelve lines in diameter, and on the posterior of six or eight. Every day's observation proves that the lens becomes flattened, and its curvatures diminished as persons advance in life. It is seen in dissection, when extracted by operation, and even during life; the distance between its anterior surface and the back of the iris being so great in some old persons, that the shadow of the pupil may be seen upon it, while at an earlier period it actually touches that part of the membrane. This diminution of the curvatures of the lens commences about the age of forty-five. Petit found the anterior convexity varying from a sphere of about seven to twelve lines diameter, and the posterior from five to eight in persons from fifty to sixty-five years of age. The alteration in power of adaptation, and the indistinctness of vision of near objects which takes place at this period, is probably to be attributed to this cause, although a diminution of the muscular power of the iris, and consequent inactivity of the pupil, may contribute to the defect. It is also to be recollected that the density of the lens is much increased at this period, and that the young person whose lens presents greater curvatures does not require concave glasses, as the old person requires convex ones. The state of the eye, after the removal of the lens by operation for cataract, proves that it is a part of the organ essentially necessary for correct vision. When the eye is in other respects perfect, without any shred of opaque capsule, any irregularity or adhesion of the pupil, or any alteration in the curvature of the cornea, as in young persons who have had the lens properly broken up with a fine needle through the cornea, vision is so good for distant objects, that such persons are able to pursue their common occupations, and walk with safety through crowded streets, but they require the use of a convex lens, of from three and a half to five inches focus, for reading or vision of near; old persons, however, generally require convex glasses on all occasions after the removal of the lens. That the curvatures of the lens are frequently different in different individuals may be inferred from the frequency of short sight, or defective power of adaptation, not attributable to any peculiarity of the cornea. Petit states that he found lenses of which the two convexities were equal, and others of which the anterior was greater than the posterior, and more than once, one more convex on its anterior surface in one eye, while that in the other eye was in a natural state. He also occasionally found the lens as convex in the advanced period of life as in youth. I have repeatedly observed the perfection of vision and power of adaptation much greater in one eye than the other in the same individual, without any defect of the cornea, pupil, or retina; and occasionally have found young persons requiring the common convex glasses used by persons advanced in life, and old persons becoming near-sighted, and requiring concaves. The annexed letters show the difference of curvature at the different periods of life, as represented by Sömmerring. *A* is the lens of the fœtus; *B*, that of a child of six years of age; and *C*, that of an adult.



The colour of the lens is also different at different periods of life. In the fœtus it is often of a reddish colour; at birth and in infancy it appears slightly opaque or opaline; in youth it is perfectly transparent; and in the more advanced periods of life acquires a yellowish or amber tint. These varieties in colour are not visible, unless the lens be removed from the eye, until the colour becomes so deep in old age as to diminish the transparency, when it appears opaque or milky, or resembling the semitransparent horn used for lanterns. The hard lenticular cataract of advanced life appears to be nothing more than the extreme of this change of colour, at least when extracted and placed on white paper it presents no other disorganization; but the lens of old persons, when seen in a good light and with a dilated pupil, always appears more or less opaque, although vision remains perfect. The depth of colour is sometimes so great, without any milkiness or opacity, that the pupil appears quite transparent although vision is lost. This is perhaps the state of lens vaguely alluded to by authors under the name of black cataract.

The consistence of the lens varies as much as its colour. In infancy it is soft and pulpy, in youth firmer, but still so soft that it may be crushed between the finger and thumb, and in old age becomes tough and firm. Hence it is that in the earlier periods of life cataracts may be broken up completely into a pulp, and absorbed with certainty, while in old persons they adhere to the needle, unless very delicately touched, and are very liable to be detached from the capsule and thrown upon the iris, causing the destruction of the organ. On this account, therefore, the operation of extraction must generally be resorted to in old persons labouring under this form of cataract, while the complete division of it with the needle and exposure of the fragments to the contact of the aqueous humour secures its removal by absorption in young persons. It must not, however, be forgotten that the softer lenticular cataract occasionally occurs in advanced life.

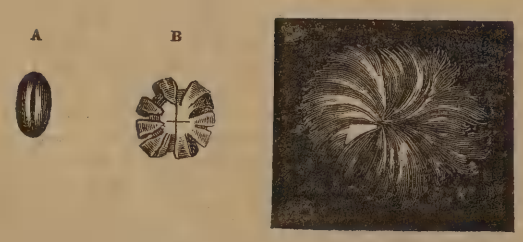
The crystalline lens is a little heavier than water. Porterfield, from the experiments of Bryan Robinson, infers that the specific gravity of the human lens is to that of the other humours as eleven to ten, the latter being nearly the same as water; and Wintringham, from his experiments, concludes that the density of the crystalline is to that of the vitreous humour in the ratio of nine to ten; the specific gravity of the latter being to water as 10024 to 10000. The density of the lens is not the same throughout, the surface being nearly fluid, while the centre scarcely yields to the pressure of the finger and thumb, especially in advanced life. Wintringham found the specific gravity of the centre of the lens of the ox to exceed that of the entire lens in the proportion of twenty-seven to twenty-six. The refractive power is consequently greater than that of the other humours. On this head, Mr. Lloyd, in his Optics, says—"In their refractive power, the aqueous and vitreous humours differ very little from that of water. The refractive index of the aqueous humour is 1.337, and that of the vitreous humour 1.339; that of water being 1.336. The refractive power of the crystalline is greater, its mean refracting index being 1.384. The density of the crystalline, however, is not uniform, but increases gradually from the outside to the centre. This increase of density serves to correct the aberration by increasing the convergence of the central rays more than that of the extreme parts of the pencil." Dr. Brewster, in his treatise on Optics, says—"I have found the following to be the refractive powers of the different humours of the eye, the ray of light being incident upon them from the eye: aqueous humour 1.336; crystalline, surface 1.3767, centre 1.3990, mean 1.3839; vitreous humour 1.3394. But as the rays refracted by the aqueous humour pass into the crystalline, and those from the crystalline into the vitreous humour, the indices of refraction of the separating surface of these humours will be, from the aqueous humour to the outer coat of the crystalline 1.0466, from the aqueous humour to the crystalline, using the mean index, 1.0353, from the vitreous to the outer coat of the crystalline 1.0445, from the vitreous to the crystalline, using the mean index, 1.0332." Dr. Young says—"On the whole, it is probable that the refractive power of the centre of the human crystalline, in its living state, is to that of water nearly as 18 to 7; that the water imbibed after death reduces it to the ratio of 21 to 20; but that on account of the unequable density, its effect in the eye is equivalent to a refraction of 14 to 13 for its whole size."

Respecting the chemical composition of the lens, Berzelius observes, that "the liquid in its cells is more concen-

trated than any other in the body. It is completely diaphanous and colourless, holding in solution a particular animal matter belonging evidently to the class of albuminous substances, but differing from fibrine in not coagulating spontaneously, and from albumen, inasmuch as the concentrated solution, instead of becoming a coherent mass on the application of heat, becomes granulated exactly as the colouring matter of the blood when coagulated, from which it only differs in the absence of colour. All those chemical properties are the same as those of the colouring matter of the blood. The following are the principles of which the lens is composed; peculiar coaguable albuminous matter 35.9, alcoholic extract with salts, 2.4, watery extract with traces of salts 1.3, membrane, forming the cells 2.4, water 58.0.

From the preceding observations it might reasonably be supposed that the lens is composed of a homogeneous material, such as albumen or gelatine, more consolidated in the centre than at the circumference; but this is not the case; on the contrary, it exhibits as much of elaborate organization as any other structure in the animal economy. It consists of an outer case or capsule, so totally different from the solid body contained within it, that they must be separately investigated and described. The body of the lens, it has been already stated, consists of certain saline and animal ingredients combined with more than their weight of water, and when perfectly transparent presents the appearance of a tenacious unorganized mass; but when rendered opaque by disease, loss of vitality, heat, or immersion in certain fluids, its intimate structure becomes visible. If the lens with the capsule attached to the hyaloid membrane be removed from the eye and placed in water, the following day it is found slightly opaque or opaline, and split into several portions by fissures extending from the centre to the circumference, as seen in fig. 2. This appearance is rendered still more obvious by immersion in spirit, or the addition of a few drops of acid to the water. If a lens thus circumstanced be allowed to remain some days in water, it continues to expand and unfold itself, and if delicately touched and opened by the point of a needle, and carefully transferred to spirit, and as it hardens is still more unravelled by dissection, it ultimately presents a remarkable fibrous or tufted appearance, as represented in the figure below, drawn by me some years ago from a preparation of the lens of a fish thus treated (the *Lophius piscatorius*). The three annexed figures represent the structure of the lens above alluded to: *A* is the human crystalline in its natural state; *B*, the same split up into its component plates; and *C*, unravelled in the fish.

Fig. 2.



This very remarkable structure of the body of the lens appears to have been first accurately described by Leeuwenhoek, subsequently by Dr. Young, and still more recently by Sir David Brewster. Leeuwenhoek says—"It may be compared to a small globe or sphere, made up of thin pieces of paper laid one on another, and supposing each paper to be composed of particles or lines placed somewhat in the position of the meredian lines on a globe, extending from one pole to the other." Again, he says—"With regard to the before-mentioned scales or coats, I found them so exceedingly thin, that, measuring them by my eye, I must say that there were more than two thousand of them lying one upon another: and lastly, I saw that each of these coats or scales was formed of filaments or threads placed in regular order, side by side, each coat being the thickness of one such filament." The peculiar arrangement of these fibres he describes as follows:—"Hence we may collect how excessively thin these filaments are; and we shall be struck with admiration in viewing the wonderful manner they take their course, not in a regular circle round the ball of the crystalline humour, as I first thought, but by three different circuits proceeding from a point, which point I will call their axis or centre. They do not on the other side of the sphere approach each other in a centre, but return in a short or sudden turn or bend, where they are the shortest, so that the filaments of which each coat is composed have not in reality any termination or end.

Dr. Young differs from Leeuwenhoek as to the arrangement of the fibres and other particulars, and in his last paper corrects the description given by himself in a former one; he says—"The number of radiations (of the fibres) is of little consequence; but I find that in the human crystalline there are ten on each side, not three, as I once from a hasty observation concluded. In quadrupeds the fibres at their angular meeting are certainly not continued as Leeuwenhoek imagined."

Sir David Brewster says that the direction of the fibres is different in different animals; the simplest arrangement being that of birds, and the cod, haddock, and several other fishes. In it the fibres, like the meridians of a globe, converge to two opposite points of a spheroidal or lenticular solid, as in the annexed figure.

Fig. 3.

The second or next simplest structure he detected in the salmon, shark, trout, and other fishes; as well as in the hare, rabbit, and porpoise among the mammalia; and in the alligator, gecko, and others among reptiles. Such lenses have *two septa* at each pole, as in the annexed figure.

Fig. 4.

The third or more complex structure exists in mammalia in general, "in which *three septa* diverge from each pole of the lens, at angles of 120 deg., the septa of the posterior surface bisecting the angles formed by the septa of the anterior surface, as in the annexed figure.

Fig. 5.

The mode in which these fibres are laterally united to each other is equally curious. Sir David Brewster says that he ascertained this in looking at a bright light through a thin lamina of the lens of a cod, when he observed two faint and broad prismatic images, situated in a line exactly perpendicular to that which joined the common coloured images. Their angular distance from the central image was nearly five times greater than that of the first ordinary prismatic images, and no doubt whatsoever could be entertained that they were owing to a number of minute lines perpendicular to the direction of the fibres, and whose distance did not exceed the 12-500dth of an inch.

Fig. 6.

Upon applying a good microscope to a well-prepared lamina, the two fibres were found united by a series of teeth exactly like those of rack-work, the projecting teeth of one fibre entering into the hollows between the teeth of the adjacent one, as in fig. 6.

With respect to the nutrition of the lens and the nature

of its connexion with the capsule, it is necessary to state that observers entitled to confidence deny the existence of vessels in its structure, and consider that it grows by imbibing new matter from its capsule. Dr. Muller of Berlin says that the capsule of the lens is its matrix, which seems to secrete the layers of the lens from its inner surface, but that this has not been ascertained with certainty. Mr. Toynbee, in a valuable paper printed in the second part of the Philosophical Transactions for 1841, says that "the mode of nutrition of the crystalline lens may be explained by supposing that the nutrient fluid is received by the cells and conducted to the lens, through which it is diffused;" it being believed that cells are either interspersed among the fibres, or that the fibres are composed of them. Notwithstanding this, I cannot admit that it is proved that the lens, or the cornea and vitreous humour, are destitute of vessels. I do not mean to deny that nutrition may be and is effected, as in the simpler forms of animal and vegetable life, without the aid of tubular vessels, and therefore cannot deny that the structures here alluded to may be so nourished; but the question is not yet settled. Microscopic observations of fluids which are easily diffused, separated, and diluted, may be relied upon; but those on organized solids not admitting of subdivision without destruction, cannot be received with so much confidence. Microscopic observers have, perhaps, been going a little too fast, and must allow us a little breathing time before we can accept all that is offered by them; and the more especially because the instrument has been laid hold of, for the purpose of display, by ignorant persons totally unacquainted with its use, and incapable of making correct observations. The question, however, of the vascularity of these structures, is not perhaps of so much practical importance, seeing that, whether vascular or not, they undergo the same changes, both in health and disease, as vascular parts do. The cornea heals by first intention, ulcerates, granulates, and cicatrizes, and the lens becomes opaque, softens, hardens, and even is partially converted into a calcareous structure. These changes I shall have to notice presently, when I come to consider the great variety of forms of cataract, and the other alterations of the lens caused by age, inflammatory action, and injury.

(To be continued.)

SKETCH OF THE LIVES AND OPINIONS OF THE CHIEF ALCHEMICAL AND CHEMICAL PHYSICIANS OR IATRO-CHEMISTS.

By M. Donovan, Esq., M.R.I.A.

(Concluded.)

Paracelsus was born in Einsidlen, in Switzerland, in 1491, or as some say, 1493. It is said that for three years he had been a sow-gelder (Gray on Hudibras). After travelling in search of knowledge, every kind of which that did not emanate from himself he ultimately condemned, he, in 1527, accepted the tendered professorship of medicine and philosophy in the University of Basil, where at the same time Erasmus was professor of theology. He had long been involved in the struggle with the Galenists; but, on his appointment to the professorship, he determined to use every effort for the extermination of Galenical pharmacy, and in his first lecture gave sufficient foretaste of the singular nature of his future career by deflagrating the works of Galen in a brass pan with nitre and sulphur, declaring at the same time that if God would not assist him he would advise and consult with the devil. He had invited a number of Galenists to his lecture, in which he promised the disclosure of an important secret: the doctors assembled; Paracelsus appeared, and uncovered a dish full of human fœces. The Galenists decamped in a fury, the professor roaring after them that they were unworthy the name of doctors if they refused to be initiated into the mysteries of putrefaction.

This remarkable man dazzled the world with an apparent grandeur of purpose which well concealed the impudence and fallacy of his pretensions. By his reckless boldness of practice with remedies hitherto untried or little used, he effected cures never before deemed practicable. To some originality and much assiduity, he superadded the most overweening self-conceit, and the most supercilious contempt of other mens' attainments. He was perhaps one of the most impudent boasters and successful impostors that ever earned so high a reputation with so little merit and so slender a stock of acquirements. Of his immeasureable vanity and carelessness of the contempt of those who could rightly appreciate his pretensions, no better proof is needed than the titles gratuitously assumed by this unblushing quack. He styled himself "Philip Theophrastus Paracelsus Bombastus of Hohenheim, a philosopher, a monarch, a spagyric prince, a supereminent astronomer, a wonderful physician, and Trismegistus of mechanical arcana." In one of his prefaces he says—"In this middle age the monarchy of all arts is given to me Theophrastus Paracelsus, a prince of philosophy and medicine: for I am chosen by God to extinguish the fantastic and presumptuous assertions of Aristotle, Galen, Avicenna, Mesue, and their followers." In the preface to his work called Paragranum, he tells the physicians that the down on his bald pate had more knowledge than all of them together; that the buckles of his shoes had more learning than Galen or Avicenna; and that his beard had more experience than all their universities put together.

To the high character which Paracelsus, no doubt, deservedly obtained for successfully treating cases deemed hopeless, by means then for the first time employed; to his unrivalled impudence in vaunting his cures; and his unmitigated arrogance in lauding his own skill in the same proportion as he depreciated that of every other practitioner of his time, may be attributed the great influence which his opinions and practice gained on the world during a period of intellectual darkness. Yet it is surprising that effrontery so unblushing, vanity so inflated, and illiberality so universal did not, by reaction, prevent rather than promote the adoption of his extraordinary opinions. Those who are anxious to discover the cause of success, in means so unlikely to ensure it, must seek it amongst the weaknesses and follies of mankind which it is not my business here to investigate.

Amongst the accomplishments of Paracelsus were astrology, geomancy, chiromancy, the art of prophecy, alchemy, the caballa, and magic. Erastus says that he cured by magic and the aid of the devil; he says his companions were devils, and that his master was the devil. Paracelsus himself pleads guilty to the impeachment, and with his usual candour acknowledges that he kept a demon confined in the hilt of his sword* for facility of consultation. The

* The notion of a spirit imprisoned in crystal, prevalent amongst professed magicians and other impostors, entertained also amongst the Rosicrucians, seems to have been of Oriental origin. The natives of South-western Australia show respect, almost amounting to veneration, to pieces of crystal which they call "Teyl." None but their sorcerers are allowed to touch them. Captain Gray notices the accordance of this word in sound and signification with the Bætyli mentioned by Burder (Oriental Customs, i., 16), which have been so celebrated and venerated in all Pagan antiquity. These ancient stones were of a round form, and were supposed to be animated by means of magical incantations, with a portion of the Deity. They were consulted on occasions of great and pressing emergency as a kind of divine oracle, and were suspended either round the neck or some other part of the body. Captain Gray adduces reason for believing that this veneration for these stones is general all over the continent of Australia, and it is remarkable that the natives have the greatest objection to show them to females.—*Gray's Journals*, .,*ii* 340, *of two Expeditions of Discovery in Australia*, 1841.

idea of a medical consultation between the devil and the doctor, at the bedside of the sick or dying, gives a singular insight into the practice and opinions which were tolerated in these days of ignorance, superstition, and credulity. He even took great pride in being accounted a magician. To further his pretensions in this respect, as well as to gratify his malignance against the Galenists and their doctrines, he declared that he had received a letter from Galen from hell, and that he had disputed with Avicenna in the vestibule of the infernal regions concerning potable gold, the quinta essentia, the philosopher's stone, and the theriaca. In these representations he seems to have been emulous of Artephius, an alchemist of the twelfth century, who, after a temporary absence, coolly informed his friends that he had been in hell in search of the philosopher's stone, where he saw the devil on a throne of gold surrounded by imps. In this instance, his satanic majesty must have departed from his usual contract with his votaries, for he had presented Artephius with the elixir of life: and accordingly the fortunate alchemist candidly confesses that at the time of writing he was a thousand years old—an age which the celebrated CountCagliostro, another alchemist, also attained, although one of his servants, who had lived with him 500 years, declared he did not think his master was quite a thousand years old yet. Such was the inestimable virtue of the elixir.

Paracelsus affirms in his Archidoxis that he never sought the common philosopher's stone, but discovered one for himself; for in everything he sought to be single in the world. The following is his process for obtaining the means of unbounded wealth:—"In the name of God, take mercury or its elements, separate the pure from the impure; let it be reverberated even to whiteness, and sublime it by sal-ammoniac until it be resolved; let it be calcined, again dissolved, and digested in a pelican for a month: then let it be coagulated into a body." Should any difficulty be found in this process he gives another:—"Let prepared amber be resolved in the stomach of an ostrich born in the earth, strengthened in its nature by the sharpness of the eagle. When the electrum is consumed, reduce it into a spiritual transparent essence: then add the tartarised quintescence, sublime it; and so the amber will be converted into the whiteness of the exalted eagle." Such are his methods of preparing the philosopher's stone; understand them who can.

For proofs of the professional veracity of Paracelsus and the very great power of the medicines employed by him, we need only refer to his own statements. He employed certain plasters called attractives, which were of such energy that one of them attracted 100 pounds of flesh like a magnet; another attracted so much perspired water from the body that it ran down as from the eaves of a house in quantity sufficient to fill a tub; another drew a man's lungs out of his body into his mouth and choked him; another drew the eye-ball out of its socket on the nose. By an attractive of this kind, he declares a cow may be lifted on high. Of such efficacy was this plaster that, as he informs us, no person ever died that had it. It would be an unpardonable dereliction on the part of his biographer to omit the composition of such a panacea: it is as follows:—"Take quintescence of all the gums in the world a quarter of a pound; magistery of the magnet six ounces; of the elements of the fire of amber (that is the electric fluid) one pound! with a few less important ingredients; make them into a cerate with wax."

Some of his styptics were equally energetic: one of them applied to a heap of stones converted them into a rock; two pieces of iron were welded together by it. A person's lips being washed with it they grew together; a certain outlet of the human body was so closed by what he calls the tricks of some sportive wag, that to procure an evacuation, instruments became necessary. This astonishing styptic was composed of quintescences of iron, of bole, of amber, with dried tartar. Elsewhere he informs us that he was called to attend a gentleman labouring under dropsy: he administered to him a diuretic of such power that the chamber where he lay was almost inundated. He declared that he could cure 200 diseases by preparations of lead, and Van Helmont affirms that this was no vain boast.

His physiological notions were as strange as his other opinions. He thought that food was not so essential as the world suppose; but his own practices showed that he considered *drink* as very necessary to maintain a man's energies. He knew a person who lived many years without any other food than ten grains of essence of gold every day. He affirms that a man will require absolutely no food if he be planted with his feet in the earth like the roots of a tree: nay, he saw a man who lived six months with no other nutriment than what he absorbed from a clod of earth placed on his stomach.

His notions concerning youth and old age are whimsically original. According to him, youth is not absent in old age, but is equally in the old man as the young. But the corruption which grows up with youth becomes so strong in old age that it takes away the vigour of youth, although the latter is still present, and then the person is old: the plain meaning of which is, that a person of 100 years of age is an old man and a child at the same instant. Admitting the hypothesis, there is no doubt that if you can separate the corrruption from an old man you convert him into a brisk youth. Now, this separation is to be made, according to Paracelsus, by means of *mercurius vitæ*, which he prepares very simply thus:—"Take mercury essentificated; separate it from its superfluities; sublime with antimony;" this, after some other processes of the same incomprehensible character, is the wonderful renovator of old age referred to.

Another boon conferred on mankind by this Trismegistus is the "arcanum of the tinctures," which takes away all unwieldiness of old age and cures every disease. It is thus made:—"Take the essence of the members, from which separate the elements; put their fire in digestion ever until nothing remain in the bottom. Then set the vessel sealed with the seal of Hermes in a moist cold place: it will soon become visible matter, which is 'the tincture.'"

If an old man can be thus readily manufactured into a young one, there is nothing to prevent his living for ever, unless some mortal disease should arrest his career. But against such a catastrophe Paracelsus has provided by the invention of his peculiar philosopher's stone; for this introduces into him incorruptible life; it even prevents "the budding forth of disease," not only in the man but in his descendants to the tenth generation, and creates the highest nobility of nature.

Another discovery of this "prince of medicine" is that alkahest so lauded by Van Helmont, which not only preserves the liver, but supplies the place of that important viscus when it is broken down and dissolved away: it cures all disorders of the liver, and in short renders it an unnecessary appendage to the body.

His "tincture of philosophers," of most important use in lues, is thus made:—"Take the rosy-coloured blood of a lion from the East, and the glue of the eagle from the South; conjoin them." This tincture, he informs us, preserved the life of some of the ancient Egyptians to 150 years.

Amongst the most sublime of his discoveries was his artificial process for making a man, which he impiously declares was communicated to him by God himself. It is as follows:—"Take a quantity of semen masculinum, seal it up in a glass vessel, and leave it for forty days to putrefy, immersed in a hotbed at its greatest heat of fermentation. Should it not become alive, and move in that time, leave it longer. After this, it will in some degree resemble a man; yet it will be pellucid, and without a body. If then it be prudently nourished, fed for forty weeks with the secret of man's blood, and conserved in a perpetual and equal heat of a hotbed, it will then become a true infant, but it will be far less in size than an ordinary infant. Then it is to be brought up until it be a stout boy, and

become wise. He says that the stars pour out a seed of which monsters are begotten, contrarily to the course of nature: we are defended from these, as well as from tempests of thunder and lightning, by the agency of bright coral.

Whether these were the ravings of a madman or the fictions of a knave, is a question of no easy solution. Yet this extraordinary being enjoyed the highest reputation as a physician; and surprising stories are related of his skill, and of the confidence which his effrontery and eccentricity inspired his patients. Being once called on to see a person who was supposed to be in the agonies of death, the doctor, after inquiring into the case, with the most perfect *nonchalance* invited the patient to dine with him next day, and to enable him to do so gave him three drops of an elixir. The patient passed a good night, and kept his appointment at dinner with his physician.

It is also reported that, with two pills, he cured a certain canon who had been given over by the faculty; but the canon seeing the cure so easily performed refused the exorbitant fee demanded. Law was appealed to, and Paracelsus was awarded only half his demand, which so disgusted him that he resigned his professorship in the university, quit Basle, and retired to Alsace, where he practised a long time with the highest character.

Of the moral character of Paracelsus, little can be said in praise. John Oporinus, his secretary, who, in the hope of discovering his chemical secrets, served him in the capacity of valet, says that during three years he had never seen him sober. He rarely took off his clothes day or night, and for two years was never known to say a prayer. He had a great aversion to the female sex, which Erastus attributes to emasculation, owing to the bite of a hog during his childhood: he had a countenance which corresponded exactly with this state.*

This eccentric being, who professed to make gold, was in his latter life little better than a beggar, and could scarcely command as much money as supplied his ungovernable propensity for drinking. He was taunted by some person, who derided his poverty, by saying that he was more than a physician (medicus) by one letter (mendicus). He that contrived a medicine which professed to cure all diseases, and perpetuate youth, became an irretrievably broken down old man a little after his prime, and after a chequered life of forty-eight years, during which he was extolled and abused, caressed and opposed, enriched and impoverished, honoured and disgraced, he that could prolong life indefinitely died (1541) on a bench beside the kitchen fire of the inn at Strasburgh. Thus were for ever extinguished the pretensions of the philosopher's stone and the elixir of life, notwithstanding the attempt of Van Helmont to revive the cheat a century afterwards.

By the bold use of mercury, antimony, and opium, Paracelsus certainly performed remarkable cures; and it is allowable to believe that he killed his portion by the rash use of these potent remedies. This clever empiric, however, gave *éclat* to chemical remedies, and even to those who employed them. At length a sect of physicians appeared who were distinguished, first by the name of chemists or iatro-chemists, and then of Paracelsians, who, as already observed, after a long contest, extinguished the sect of Galenists. The opinions of the Paracelsians continued but a short time popular, and towards the close of the seventeenth century ceased to be entertained; yet the sect bequeathed, perhaps to the latest posterity, that predilection for chemical remedies by which they were first rendered remarkable. Notwithstanding the insane vagaries of Paracelsus and his followers, we owe them grateful acknowledgments for the introduction of remedies capable of curing diseases which, under the treatment of the Galenists, would certainly have proved mortal. From the time of Paracelsus to the present day, chemical remedies constitute not only the majority, but by far the more energetic portion of therapeutic agents; and our present accomplished race of physicians are to be considered, with regard to the employment of remedies, as representing the iatro-chemists of the sixteenth century.

In bestowing attention on the almost incredible extravagancies of this curiosity of human nature, we have not committed the puerility of amusing ourselves with a mere history of hallucinations: we have been virtually contemplating the age in which he lived; for with whatever disgust or compassion we view the impostures or delusions of that miserable eccentric, with equal surprise and humiliation must we contemplate the benighted condition of mankind when such a being was deferred to.

The next alchemistic physician whose career attracted much of the notice of the world was Van Helmont, born of a noble family in 1577 at Brussels. He seems to have been a man of irregular mind and habits, in this respect somewhat resembling his predecessor, of whom he was an admirer, and to a certain extent an imitator, boasting of the possession of many secrets in common with that magnificent impostor. One of these was the alkahest or universal solvent. He declares that he had performed the process of transmutation, that he projected a quarter of a grain of the powder of projection on eight ounces of hot quicksilver, that the quicksilver immediately ceased to flow, and became as solid as wax. After this process he found the whole converted into the purest gold, weighing almost exactly the same as the original quicksilver. He also declares that he frequently repeated the process before witnesses. These assertions stamp the character of Van Helmont. Yet he was a man of superior attainments and power of mind. He was regularly educated as a physician at Louvain; at 17 he gave lectures in surgery; and before he was 22, when he graduated in medicine, was well versed in the medicine of the Greek and Arabian schools. He was of opinion, and brought forward ingenious but fallacious experiments in support of that opinion, that the three kingdoms of nature, animals, vegetables, and minerals, are composed of water alone, disguised by the plastic virtues of their seeds. As to his physiological opinions, they are not worth notice in the present day. In his practice, he was much addicted to the employment of empirical remedies. As if in imitation of the irregular habits and inordinate boasting of Paracelsus, whom he so much admired, he wandered about from place to place acting in the capacity of an empiric, and employing extravagant modes of cure; but to his credit be it recorded that he did not accept fees, for contempt of money seems to have been one of his redeeming qualities. At last he settled down into the quiet pursuits of his laboratory, and died at the age of 67.

I have now brought under notice the most remarkable of those physicians who practised or believed in transmutation, and shall conclude with some general remarks.

The doctrine of the alchemists afforded a good instance of the danger of hypothesis. It was *assumed* that all metals are fundamentally the same, that their differences are attributable to foreign matter, the removal of which constitutes the art. According to the fashion of the times, antecedent to those of Bacon, facts were sought to support the assumption; and failure was attributed to inadequacy of the means, not to the fallacy of the hypothesis.

Amongst the alchemists there were men who honestly believed in the possibility of transmutation—men of superior intellect, education, and attainments, who unintentionally deceived themselves and others. Giovanni Aurelio Augurelli, already mentioned, was a remarkable instance. He received his education at the University of Padua, and had the reputation of being one of the most learned men of his age. He was an elegant Latin poet, and his Chrysopœia has been pronounced by good judges to be worthy of the person to whom it was dedicated—Leo X., himself an enthusiastic admirer and writer of Latin poetry.

There was no class of the community, except the poorest, exempt from the prevailing contagion—kings, parliaments, nobles, persons of the most exalted rank, were the

* A cast of his head, taken from the skull at Salzburgh, is preserved in the University of Vienna.

chief dupes. Dr. Fauceby, physician and alchemist to Henry VI., received his commission to search out the philosopher's stone and universal medicine from the king himself, and it was confirmed by his parliament. A royal laboratory was fitted up for his researches. The rose-nobles, coined by order of Edward I., from gold made by Raymond Lully, existed, although scarce, in the days of James II.; a large quantity of them was carried to France by that unfortunate monarch, unsuspicious of their intrinsic worthlessness. The empress Maria Theresa empowered Professor Jacquin to receive proposals from all persons who proposed to make gold, and to provide them with every requisite at her Majesty's expense. Her husband, Francis Duke of Lorraine, expended vast sums in the pursuit, and in the absurd attempt to make large diamonds by melting small ones. Queen Christina of Sweden, maintained a court alchemist, and squandered her income in the same manner after her abdication. Frederick, king of Poland, sought to relieve his embarrassments through the aid of alchemists; but being deceived by one of them, he cut off his head.

Some alchemists professed other attainments; James IV. of Scotland entertained at his court a French physician and alchemist, who was also an abbot, and who so far imposed on the monarch and on himself as to undertake to fly to France, and thus get the start of certain ambassadors. The wings were made, fixed to him, and away he flew from the walls of Stirling Castle—as far as the ground; for falling down he broke his thigh bone, and could assign no other cause for his misfortune than that there must have been some hens' feathers in his wings. (Tytler i., 335). Lorenzo Ferrer Maldonado, another of this higher class of pretenders (1609), announced that he had decyphered Solomon's seal, which enabled him to produce a philosopher's stone of the highest perfection. A large sum of money being placed at his disposal, he prosecuted his labours for two years, produced nothing, and disappeared. Count St. Germain, a celebrated alchemist at the court of Louis XIV., invented an elixir, which, obviating the effects of age, prevented any disagreeable disclosures through the agency of time on the colour of the hair, without any staining process.

The early alchemists thought that none but the pious and upright were worthy of the secret of the philosopher's stone and elixir of life. Even so lately as the end of the eighteenth century Mr. Peter Woulfe, a really ingenious man and skilful chemist, being intently occupied in the search of the elixir, attributed his repeated failures to the want of due preparation by pious and charitable acts. It is told of him that such was the confusion in his apartments of boxes, packages, furnaces, and all sorts of apparatus appertaining to his pursuits, that a gentleman who came to visit him unfortunately laid his hat out of his hand and never could find it after (Brande).

The notion of transmutation is far from being banished from the world. In eastern countries, splendid promises still urge forward disappointed expectation, and alchemists are almost as common as any other class of impostors. Sir George Keppel informs us (Personal Narrative) that in the neighbourhood of the Elwund Mountain in Persia, the belief is general that there is a certain grass which has the virtue of changing every metal into gold, and that the mountain contains the philosopher's stone. On this mountain is a large mass of granite on which is an ancient Babylonish inscription containing the history of the treasure, which, they say, is buried near this spot, and which will never be discovered until the mysterious writing be decyphered.

I have somewhere read of an alchemist who proposed to a rich merchant to communicate the secret of gold-making on being paid a large sum. The agreement being made, the process was performed with gold provided and the money paid. One of the articles made use of was earth brought from the mountain above mentioned, which earth had been purchased at one of the Persian markets by the merchant's own servants. The alchemist, having secured the payment for his services, took his leave with remarkable alacrity; the merchant forthwith commenced the process of making an extemporaneous fortune, and sent his servants to purchase all the earth that could be procured at the same market. But those who had previously sold it, being confederates of the alchemist, had decamped; no one there had heard of such an earth. The truth was that filings of gold had been mixed with the earth previously procured.

There are alchemists in the present day, in eastern countries, who perform their legerdemain tricks with impenetrable astuteness. The following account, given by Mr. Frazer (Travels in Koordistan), is worth recording. The transmutation was performed, after several months of preparation, before the pacha of Bagdad and the master of his mint, M. de Marquez, a remarkably clever man. M. de Marquez, suspecting the alchemist to be a rogue, provided the materials—viz., brass, and a very little arsenic, both of which, with his own hands, he put into the crucible; he examined the charcoal, and had the process conducted in the laboratory of the mint. The alchemist did not even approach, except to throw in a powder, less in quantity than a small pinch of snuff. M. de Marquez then poured out the melted metal. The redundant brass being removed, the gold produced weighed one-third of the brass and arsenic made use of, and, when assayed, proved to be perfectly good and marketable.

In concluding this history, I may be permitted to observe, that notwithstanding the astounding absurdity of the opinions promulgated by the persons whose names have been introduced—all of them of high repute in their day—they have been quoted with rigid exactness from competent authorities. I may further add, that in a few cases I have taken my statements at second-hand; the original writers in all other instances, and in no inconsiderable number, have been referred to, without which means of certainty, in the chief matters brought forward, I would not have presumed to occupy the attention of the reader.

ON TEETHING.

(From a Treatise on the Teeth by Mr. A. Canton.)

The process of teething, as the eruption of the temporary and permanent set of teeth is termed, is one of the utmost interest and importance to the medical attendant, the anxious parent, and to the child itself. In very many instances it unfortunately happens, that the absorption of the gum, and dental sac, set up by the onward progress of the advancing tooth, excites great irritation and fever in the animal economy, which not unfrequently settles in some one or other of the more important organs of the body, and induces disease, which, if not speedily combated by the resources of the medical art, may either lead to permanent and irretrievable mischief, or to the absolute destruction of life. It behoves then all who are interested in the welfare of children, to watch carefully at this period of their infantile existence for the signs and evidences of commencing irritation in any part of the system, and as soon as they appear, however trifling they may be, more especially if there be heat and swelling of the gums, with the other symptoms of approaching teething, at once to seek for that medical assistance, by which alone the impending mischief may be warded off.

We have already given a brief sketch of the development of the teeth during the period the embryo is carried in the mother's womb, and have brought up our remarks to the time prior to dentition. The teeth continue to grow after the birth of the child, until, in the average of instances, the crown in full growth makes its appearance externally, having caused, by the pressure it exerts, the removal of all the parts lying over it. The fang is not complete until after the crown of the tooth has presented itself above the level of the gum. Before this occurs, certain changes take place in the gums, which indicate to the experienced eye and finger, that nature is urging forward the eruption of a tooth. The gum becomes broader, swollen, hot, and tender; the child is constantly dribbling, and is

never easy unless it has a finger, or some substance in its mouth, to press upon the inflamed gum. Much pressure, however, causes a fit of crying, and the little sufferer frequently in addition presents signs of general irritation and irritability. It is fretful, frequently crying, and is pacified with difficulty; the cheeks are flushed, sleep restless and disturbed, and the stomach and bowels are more or less disordered. In some instances, however, the teeth are cut with little or no disturbance of the health, and almost the first indication given that the process of dentition has been going on, is the appearance of the tooth above the level of the gum.

The first teeth of the temporary set are cut in general about the sixth, seventh, or eighth month of infantile life; these are the central incisors of the lower jaw, and they are followed in the course of a week or two by the same teeth in the upper jaw. It should be fully understood, however, that in stating the sixth, seventh, or eighth month, as the period when these teeth are first seen in the mouth, the average is taken of the process of teething in healthy children. Teeth have been cut much earlier, and again the process has been delayed till the tenth, and even the twelfth month, the time of their appearance varying greatly in different children, owing to the state of their health, their freedom from disease, hereditary or acquired, the strength of their constitution, &c. Again some children cut their teeth across, as it is termed, that is to say, certain teeth appear above the gum in an order different to that usually met with; the canine perhaps before the incisors, and certain of the molar teeth are found to be making their way most irregularly.

In the usual course of nature, however, the central incisors of the lower jaw are cut about the time already stated, and their appearance is followed some days afterwards by that of the corresponding teeth in the upper jaw. The lateral incisors of the upper jaw next make their way; this occurs about the tenth or eleventh month, and those of the lower jaw soon follow. A month or two after these, we have the anterior molars of the lower jaw piercing through the gum, and soon after those of the superior maxilla. The canines next appear, and lastly the second milk molars, between the age of two years and two and a half.

The irregularities so often encountered among the permanent teeth, are rarely met with in the temporary, either as regards position, number, form, or date of eruption. The well-known, but somewhat apocryphal tale respecting Richard III., has, however, had its parallel of late date. Tomes mentions a child, five weeks' old, whose mother complained that it was born with two teeth in the lower jaw, by which her breast, and its own upper jaw, had been injured. On examination, he found two sharp-edged, rough-surfaced incisor teeth sticking up from the centre of the lower jaw. They were ill-shaped, imperfectly coated with enamel, and loose in the gum, and stood across, instead of in a line with the alveolar arch. These were removed, and it was found that the fangs were not more than one-third developed. In fact, the teeth had attained about the normal amount of development for the age of the child, but had been protruded through the gums before they were fitted for eruption. An after-process had been effected before the preparatory one had been completed. A similar case has occurred in my own practice.

Dr. Brown, an American physician, mentions a still more extraordinary example, which he published in the *American Journal of Dental Surgery*. A child was born with the central incisors through the gums. They were extracted. Two other children were afterwards born of the same mother, in each of whom the same singular anomaly was found. Their teeth were allowed to remain. In each case the children were females. Dr. Crump, another American physician, reports a case of full dentition, at birth, in a still-born negro child. The sockets were very imperfectly formed. Dr. Lethbridge, it is said, has met with a similar instance.

Imperfections in dentition are of occasional occurrence. Sometimes the central incisors are absent altogether; in others again, even when the child has attained its sixth year, it may have a few front teeth only. Two cases have been recorded in which the persons reached old age, without even cutting a tooth. In a case exhibited by Dr. Brinton at the Pathological Society, the alveolar processes of the upper jaw-bones were wanting, but the canine teeth were present on each side, lying parallel to the maxilla. I myself examined a child, whose mouth was apparently well formed. Nevertheless I detected the absence of the right canine tooth of the lower jaw during the first dentition. This was a deficiency that a dentist or a surgeon only could detect, as the jaw appeared to possess its full complement of teeth, there not being any vacancy in the place where the canine should have been found. As I looked upon this as an interesting specimen of dental pathology, I made a model of the mouth, which is now in the possession of my friend, Mr. Tomes.

It has been already stated that the irritation caused by the process of dentition will, in many children, induce disorder, and even permanent disease of other, and important organs of the body. The first signs indicative of the commencement of that process are mostly attended by fever, and general disorder of the system. The child is irritable and fretful; the skin hot and dry; the bowels disordered; the scalp hot; the eyes heavy and dull, or preternaturally bright; the mouth slavers, the gums are swollen, broader, and more red than usual, hot and painful to the touch: the appetite is lost; the little patient taking the breast by fits and starts, and speedily losing its hold of the nipple. The bowels are generally disordered, the stools being relaxed, and often of a pale, pasty appearance, or green, or clay-coloured. Frequent purging, with griping pain, is not an uncommon concomitant of dentition. The head, however, may be the part that sympathises most during teething; when the irritation has been continued for some little time, or even very early during the attack, the infant may be seized with convulsive fits, recurring often with great rapidity, and ending not unfrequently in death, if the appropriate preventive, and remedial measures, be not adopted. A less severe form of disorder, thus induced, may, however, attend on this cause of irritation; eruptions on the scalp, cutaneous inflammations, and discharge from behind the ears, inflammation of the eyes, &c., all in childhood owe their origin at times to the concomitant disorder of dentition. Water on the brain and epilepsy, generally of a temporary, but sometimes of a permanent character, may be thus excited. Again palsy, affecting one or more limbs, may be induced, and may become permanent, or even prove the precursor to a fatal termination.

On this point, Dr. Henry Davies, late of Saville-row, Physician to the British Lying-in Hospital, and now of Brighton, has added his testimony in proof of the very serious diseases which are sometimes set up in consequence of dentition. In a communication, which he addressed to the Medical and Chirurgical Society, he describes the case of a female infant, rather more than a year old, who had cut two lower teeth well; but who one day, having been previously very lively, and having taken her usual exercise in the baby-jumper, and been put to bed apparently well, soon after became restless, and slightly shivering. Early the next morning, she uttered a peculiar cry, and the nurse gave her some Dalby's carminative. This not affording any relief, she was put into a warm bath, and had a dose of castor oil. A few hours after, she was violently sick, turned cold, and looked blue about the mouth, nose, and eyes. She was then put into a warm bath again, when she appeared to lose the entire use of her limbs, and her countenance became vacant. Dr. Davies did not see her till the evening of the second day,—much valuable time being thus lost. She was perfectly conscious; head cool, and the temperature of the surface generally natural, the pupils contracting under the influence of light: pulse moderately frequent, small and languid: tongue slightly coated. The upper extremities were devoid of all power of motion, or sensation, even from pinching or pricking with a pin; but the lower extremities were drawn up on her feet being

tickled. Nothing unnatural could be detected in the spine or elsewhere. Leeches had been applied behind the ears; a blister was placed between the shoulders, and aperients, &c., were administered. During the five weeks that the child lived, no change took place in the paralytic symptoms, and she remained conscious to within a few hours of death. During this time she cut six teeth. The appearances after death showed some degree of determination of blood to the brain, which, with the upper part of the spinal marrow, was peculiarly firm. There was an ounce and a half of sanguineous fluid covering the surface of the brain.

In commenting on this very interesting case, Dr. Davies stated that palsy, coming on suddenly, not preceded nor accompanied by any apparent disease of the brain, is by no means uncommon in children between the first and tenth years. In all these cases, he believes—and facts fully demonstrate the truth of his opinion—that the predisposing cause is the process of dentition. The exciting or immediate cause has, he says, in the majority of cases, appeared to be some derangement of the digestive organs. In this peculiar case, he remarks that the exciting cause was the succession of shocks received by the spinal cord through the use of the baby-jumper.

This interesting and valuable instance of palsy occurring in an infant, bears directly on the statements that have been advanced respecting the dangerous consequences of neglected dentition. Had this poor little sufferer been subjected to the innocuous and highly beneficial operation of lancing the gums on the morning she was taken ill, it is more than probable that all the serious symptoms which ensued would have been prevented, and the infant still alive to rejoice the hearts of its parents. That the distress and nervous derangement dependent on dentition were the predisposing cause of the palsy, we have the authority of a distinguished physician, whose energies and medical knowledge have been especially directed to the investigation and treatment of the diseases of women and children, for believing. Every fact in physiology and pathology at all bearing on the subject confirms this opinion. The cases yet to be narrated, and the facts which have been already made known, are such as not to admit of any doubt upon the subject. Warm baths and aperients, and the application of leeches, were relied on to remove a disease affecting the frame generally, and the nervous system especially, while the simple but most efficient remedy, lancing the gums for the removal of the local cause of this general mischief, was apparently wholly neglected; at all events, no mention is made of its performance in the records of the case in the medical journals; it is therefore only fair to presume that it was not had recourse to. In this respect no blame attaches to the medical men, as their assistance apparently was not sought until the domestic pharmacopœia had been exhausted, and the disease was fully established. It is much to be regretted that the non-performance of this trifling operation led to the sacrifice of a human life, but it is to be hoped that the record of the painful results following its neglect will serve to open the eyes of parents and nurses to the folly of which they are guilty, in offering a sustained and almost systematic opposition to lancing the gums—a proceeding which has been the means of preventing, and of removing, a vast amount of infantile disease, and consequently of saving many lives.

Similar testimony is borne by Dr. Marshall Hall, in his work, On the Diseases and Derangements of the Nervous System, in which he has published the case of a little girl, twenty months old, a daughter of Dr. Grant, of Thayer-street, who, while suffering from dentition, lost the power of elevating the right arm—that of closing the hand and of bending the forearm remaining. There was not any symptom of brain affection present. The case was clearly one of palsy from teething. The gums over the four eye-teeth, which were all coming forward, consequently were freely lanced every second day; the bowels well moved, and the diet strictly regulated. For fear of hidden disease within the head, two leeches were applied. A few days after the attack of palsy, the little girl was seized in the early part of the night, with a fit of crowing inspiration. This confirmed Dr. M. Hall in his opinion as to the cause of the attack, and the event justified the view he had taken. The child recovered perfectly, without any energetic remedy being used for the cerebral affection, by continued attention to the state of the gums, the stomach, and the bowels; an event, he says, which could scarcely have occurred from such simple measures, had there been such decided affection arising from disease of the brain. The palsy and the cough completely disappeared when the four teeth made their appearance in the mouth.

(To be continued.)

POPLITEAL ANEURISM TREATED BY PRESSURE AND DELIGATION OF THE ARTERY.

(Under the care of Mr. Hilton of Guy's Hospital.)

Whenever we notice a case of aneurism, situated on a limb, in any of the hospitals of London, we follow the treatment with peculiar interest, for the question as to the best method to be adopted is far from being solved. Every one will agree that the safest way of arriving at something like a solution is the careful watching of the results of certain lines of treatment, and the exact observation of the nature of the complaint, as well as the peculiarities of the patient. Since we feel perfectly unprejudiced as to the value of compression or deligation, we are enabled to observe with an unbiassed mind, and shall have much pleasure in laying before our readers, *all* the cases which may fall under our notice. In the present state of the question, it must be apparent to those who have given it some attention, that both methods possess advantages, that neither should be undervalued, and that the skill principally consists in distinguishing the method best suited for a given patient.

As to pressure, it will doubtless become more and more clear that it should be very gradual, and that the locality chosen for applying it should, as far as possible, be such as not to include the vein. Those who are inclined to be enthusiastic about pressure should, however, recollect that cases occur where the slightest restraint is unbearable (we shall soon have to report a case fully illustrating this point), and that pressure, as well as the ligature, has its disasters. As an example of this fact, we would just allude to a case which was treated some time ago by Mr. Busk, surgeon to the *Dreadnought* hospital-ship. Here, as we are informed by Dr. Beith, R.N., pressure was made on the femoral artery for popliteal aneurism, and for a time apparently with success. Pulsation in the tumour had ceased; and just as Mr. Busk fancied the cure would be complete, gangrene of the limb set in, and death was the issue. The case which we have now to put upon record is replete with instructive facts, and we hasten to offer a brief sketch of the same. The notes were taken by Mr. Fuller, one of Mr. Hilton's dressers.

Hugh M——, aged 43, a man of spare make and nervous temperament, was admitted into Luke ward, Dec. 21, 1850. As a porter of hops, he was in the habit of straining his legs considerably. For some time past the patient has not drunk to excess, but formerly he was very intemperate, and on being closely questioned as to any blow or injury he may have sustained, nothing of the kind is discovered. One year ago the leg and ankle swelled at times, and nine months since the patient perceived a swelling like a walnut in the ham of the left leg. No attention was however paid to this symptom, until a fortnight before admission, when such sudden pain seized the patient, that he could not place his leg on the ground; and he now, for the first time, noticed a pulsation in the popliteal tumour, the latter extending from the ham to the calf of the leg. The pain has since become much worse, and includes the whole thigh and leg.

On examination, a deep seated, soft, fluctuating, and pulsating tumour was discovered, extending from the popliteal region into the calf of the leg; it diminished in size

by pressure on the femoral artery, and the reverse happened when the artery was compressed below the tumour. The usual symptoms of popliteal aneurism, including a distinct bruit, were present.

Mr. Hilton prescribed rest, an elevated position to the limb, the pain to be combated with opium, and the thigh and leg to be carefully bandaged from the toes upwards. About a fortnight after admission, Mr. Hilton had an apparatus applied for the compression of the artery. It was composed of two separate instruments: the one, fixed to the pelvis, was intended to press on the artery in its course over the head of the femur; the other, applied to the thigh about half-way down, was to compress the vessel in Scarpa's space. The pulsation was not arrested by the use of these instruments, but only moderated.

The patient bore the pressure pretty well, complained only of a little cramp in the leg, and stated that the acute suffering he experienced in the limb before the apparatus was put on, was now quite removed. On the third day after the commencement of pressure, scarcely any bruit or pulsation was left in the sac, the latter was less tender and swollen, and the patient could almost straighten his leg, though he had in it a sensation of numbness and tingling.

On the fifth day he began to feel uneasy and complained of the pressure; the pain in the leg had returned, the tumour was larger and softer, and the pulsation much more forcible. On the eighth day the pain in the leg and foot was much increased, and at six in the evening the suffering was so intense that the patient could not bear the pressure or even allow the limb to be touched; the apparatus was, therefore, removed, and a drachm of laudanum administered.

Mr. Hilton now directed digitalis to be given internally, and ice to be applied to the outer side of the tumour. The ice gave much pain and was discontinued. The tumour was, however, becoming larger,, and the pulsations scarcely perceptible on the inner, but more distinct on the outer side. On the tenth day after the first application of pressure, Mr. Bransby Cooper, Mr. Cock, and Mr. Hilton, held a consultation on the case, and it was agreed that the artery should be tied in the upper part of the thigh.

The operation was, however, delayed for a couple of days, as active inflammation was going on in the artery and limb. The thumb lightly pressed on the femoral artery caused intense pain, both in the course of the vessel, and the whole limb; it might thus be conjectured what distressing symptoms the ligature would occasion. The patient was placed under an antiphlogistic treatment, with purgatives, &c., and as pressure could no longer be borne, Mr. Hilton had no alternative but to tie the artery (under unfavourable circumstances) or remove the leg. The first of these measures was preferred, and Mr. Hilton put a ligature on the femoral artery, about the middle of the thigh. The coats of the vessel were found much thickened and infiltrated; the patient was at once put into a warm bed, the foot and leg comfortably wrapped up in flannel.

Half an hour passed in comparative ease, when suddenly pain of the most intense and agonizing kind in the whole of the left thigh and leg seized the patient. Large doses of opium were administered, and chloroform inhaled two different times without alleviation. Opium given continuously at last procured sleep, and the patient rested the whole night and part of the following day. The man now complained no longer of pain, but of numbness; the tongue became brown and dry, and the pulse beat 110, small and weak.

On the third day after the deligation of the artery, the pain was absent, the patient slept well, the tumour became harder, diminished in size, and the pulsations did not return. Matters went on very favourably until the tenth day, when shivering occurred, and pain arose in the foot, which was now beginning to fail in keeping up its proper temperature. Wine was now ordered, and the pain having two days afterwards become very violent in the leg and around the knee, Mr. Hilton made a small opening in the sac at its inner and lower part, and allowed three or four ounces of dark, grumous, exceedingly fœtid and purulent blood to escape.

Some effusion around the knee-joint was now noticed; a small opening was therefore made on its internal and inferior aspect; but no freeing of matter ensued. Pain and stiffness in the left *elbow-joint* were now complained of: a little more blood was allowed to issue from the aneurismal sac, and a plug of lint placed in the aperture. The patient now took as much as twelve ounces of wine a day, and though the pain in the elbow-joint diminished, it now declared itself on the shoulder, and intense heat attacked the affected leg and foot: pulse 130, irregular.

On the 1st of February, being the fifteenth day after the application of the ligature the pain had ceased, but the patient was extremely depressed; the toes on the left side, with a great portion of the foot, became insensible, and of a mottled purple colour; the wound of the thigh remained stationary and the ligature firm.

On the 18th day the general symptoms were worse, the gangrene spread over the whole foot and half-way up the leg; several vesicles formed, and a quantity of bloody serum escaped from some of these. A line of separation appeared to form a little above the middle of the leg; but the patient, in spite of the stimulants which were plentifully given, became so exhausted that he died on the 22nd day after the deligation of the artery; one month after the application of pressure, and six weeks after admission.

On a post-mortem examination, pus was found in the elbow, shoulder, and knee-joints. The viscera were tolerably healthy, and no ossific deposit was observed in the femoral or any other artery.

After the perusal of the foregoing case it will become evident that pressure is a very unfavourable forerunner to the ligature, and that there are patients with whom all methods of treatment, from nervous susceptibility and want of tone, fail of yielding good results. Pressure is now being tried at the London Hospital on a patient of Mr. Ward. The man is of a middle age, of a good constitution, and affected with popliteal aneurism. Mr. Ward is bestowing especial care upon the case, and has procured the new compressing instrument lately invented by Dr. Carte of Dublin. We shall watch the case with much interest, and endeavour, in reporting it, to render it practically useful to the profession at large.—*Lancet.*

CORRESPONDENCE.

THE MEDICAL CHARITIES' BILL.

TO THE EDITOR OF THE LEINSTER EXPRESS.

Dear Sir,—The reference made to the Queen's County Infirmary in the letter of your London correspondent in your last publication, in his outline of the proceedings in parliament on the subject of the Medical Charities' Bill, appears to render it imperative on me to make some explanation. I have not, I believe, offered any observations to the public on the bill of this session or the last; yet I have not been a passive observer of the measure, nor altogether inactive in respect to it.

I may remark that no more decisive example of the inefficient and ignorant manner in which English legislation is conducted in respect to Irish affairs could be adduced, than these Medical Charities' Bills, in the various Protean forms in which they have been presented to parliament. The first is at this moment before me, bearing date May 23rd, 1837. Endorsed with the name of—whom?—William O'Brien! and Lord Morpeth, upon the back. From that time to the present, various bills have been brought forward—by how many ephemeral Irish secretaries in succession?—and have proved abortive. The cause was obvious. The real propounders of these measures—the pullers of the strings—were not men of upright principles and honest intent, and the consequence was, that in their attempts to accomplish objects of their own, they led their parliamentary supporters into difficulties, and produced measures that were repudiated by the legislature. I do not believe that men practically acquainted with the subject, more especially those resident in country districts, were once consulted; the subject was handled almost exclusively by waiters on Providence and on patronage; and of late the matter has been descending to the waiters on them.

Now, even the man floated towards the surface by "famine and fever" turns his back upon it, and leaves it to the smaller fry, who followed in his wake, encouraged by the fœtid fragments of patronage flung to them during the existence of the Temporary Fever Hospital Act.

Your correspondent states that, in the course of the debate, the Infirmary of the Queen's County was named "as an example, that comparatively few brought from a distance were relieved in it," and a reference was made to the report on the Irish Medical Charities in support of the statement. I would ask, have the innumerable instances in which that report has been *proved* to be untrue been forgotten so soon, or is it merely because it appears in the garb of paper and print that it is referred to as an authority? I do not doubt that the honourable member supposed his statement to be correct, for such gentlemen do not always recollect that their prompters are unscrupulous, if there appears to be a chance of the object being attained.

I will trespass upon you with only a very brief outline of the statistics of the infirmary here. I find that the average number of in-door patients, for each of the last ten years, has been 1166. Of these, 431 came from within a circle of five miles radius round the infirmary; 472, from a circle between five and ten miles, and 263 from beyond a circle of ten miles. I have laid a measure to the map, and find that the county extends beyond the radius of ten miles in very few points, and to a very limited extent. The average of expense for the period of ten years—and a very expensive period it was—has been £17 1s. for each bed kept full throughout the year, and £1 3s. 8*d*. for each individual treated in-door, including all expenses of rent, bedding, clothing, food, salaries, medicine, &c. There are, at this moment, seventy patients in the infirmary, including cases of accident, medical and surgical diseases, and fever in its most serious form. I may challenge a comparison of its condition with that of any hospital, metropolitan or provincial, in the united kingdom, and there are few worth being visited which I have not seen. The institution is under the control of governors and governesses the most respectable, to the number of one hundred and sixty-three, while our annual income from voluntary contributions alone, has been over £200 for each of the last ten years.

I ask you is it excusable to experiment on an institution conferring so much benefit, and circumstanced as this? Can it be apprehended that it shall fall a sacrifice to men seeking for commissionerships and inspectorships? manufacturers of bills, who have been too idle to apply their energies to the legitimate practice of their profession, but have grizzled and grown white in dozing expectation that something might turn up. I cannot believe that such will occur; even though I have seen corruption prosper, and knavery and idleness meet reward.

The Queen's County stands indebted to her two members and to the honourable member for Portarlington, for their exertions to preserve the infirmary from being seized: all resisted the aggression. Much attention has been given by them to the question which they understand so clearly, as to enable them to exercise the most useful protective influences in regard to future stages of the bill.

It is alleged that there are many counties in which the infirmary is placed in an extreme and remote point. A reference to the map will, however, show that the instances are few. Existing laws provide for such cases, by conferring powers to establish a second infirmary where required. Population has diminished—*dare it be stated how much?* Workhouse hospitals and fever hospitals have been established, and facilities for medical relief undoubtedly increased. These facts, however, matter not; the medical commissioner and inspectors are ready, with their secretaries and clerks, messengers and servants, and the public still has a very long purse. I do not profess to address myself to this question as a matter of finance. I do not intend to sail or serve under colours that are false—my object is to correct misstatements and to act on the defensive against the real parties in the case, who, I am convinced, are seeking their own ends alone. I leave to Sir Wm. Somerville an explanation of the fiscal details. I leave to those who have experienced the perfections and pleasures of relief works and poor relief, to reflect on the probability of a judicious and well-regulated retrenchment, which I present, with my best respects, to the medical attendants of fever hospitals and dispensaries, Sir William's announcement that the dispensaries are to be reduced by 228 only, and from the hospitals 30 are to be taken off; with a liberal allowance of £95 for each dispensary, to cover house rent, medicine, doctor's salary, servant, and other details. Are the men blind not to see the inevitable result of the shuffling and dealing of the new pack? Are they deaf to the howling and yelping of the wolves and foxes, impatiently waiting for the bone which is complained of as being already too bare?

Your correspondent stated that allusion was made to a reduction of two hundred pounds by the presentment sessions, on the sum applied for, for the support of the infirmary in this county. This amuses me not a little, as proving how hard up are the supporters of this bill to sustain their allegations by facts. Those who were to be made men by the bill, sounded the tocsin that the institutions were to be undone—that the supplies were being stopped. The value of their statements may be judged by observing that the case is bolstered up by an allusion to a reduction of one hundred—not two hundred—pounds, by the presentment sessions of the Queen's County—at the instance of a gentleman, comparatively new to our county, and inexperienced in its affairs. But the allusion proves more—that there is a prompter at every elbow, and that the promoters of the bill have their emissaries, moving about in every direction, in coloured clothes. It may be satisfactory to add that the usefulness of the infirmary was unimpaired, that it continued in the same vigorous state of efficiency in which it had, by the intelligence and liberality of this county, been previously established and maintained.

You are aware that very few months since, the newspapers were filled by reports and resolutions of a meeting of the medical profession, at the College of Surgeons, in support of this bill. These were put forward in a form calculated to lead to a belief that they expressed the unanimous sentiments of the profession; such, however, was not the fact. The requisition was so framed as to admit of the attendance at the meeting of the medical attendants of fever hospitals and dispensaries only—and of these those only who were *favourable* to the bill.

I am not to be supposed as by any means objecting to legislation on this subject. That honest inspection and truthful reports would prove useful, I firmly believe. That there are many districts in which efficient medical relief cannot be provided for the poor, under existing laws, I am not prepared to deny, though not by any means, as yet, convinced of the fact, especially when I bear the more recent amendments of the poor-law in recollection. But I do contend that it is eminently impolitic and inexpedient to interfere with the general principles of the constitution of the infirmaries. They should, in fact, be excepted from the bill unless as relates to inspection, and placed in the same position as the County of Dublin Infirmary, and certain hospitals of Dublin, good, indifferent, and decidedly bad, as they are, whose exemption has been secured by the ingenuity of certain tacticians of the city, who did not fail to take care of themselves.

Let me, in conclusion, be permitted to observe, that in any part I have taken in connexion with this matter, I have not in any manner interfered, with fever hospitals or dispensaries. I left them, for my part, to the guardianship of their own officers, for whom, as a class, I may with truth and earnestness declare I entertain, more particularly in this county, the utmost good will and respect, as containing amongst its members men whom I highly esteem as of honour as unimpeachable, and motives as elevated as are to be found in any body of people in any portion of the British empire. —Believe me, dear sir, to be your very faithful servant,

JOHN JACOB, M.B.,
Surgeon to the Queen's County Infirmary, &c.

IMPORTANT INQUEST.

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—I would be greatly obliged by your giving insertion in the MEDICAL PRESS to the enclosed evidence and verdict taken at an inquest on the 4th of June last.

Yours respectfully, JAMES TAYLOR.

Bailieborough, 3rd July, 1851.

ON the 2nd of June last, Dr. Taylor of Bailieborough served, a requisition on John McFadin, Esq., coroner, also on James L. Bailey, Esq., sub-inspector, to have an inquest held on the body of the late John Jackson, who had been interred on the 19th of May near Bailieborough, and who, it was currently reported, had died from the effects of medicine prescribed for him by Dr. Taylor.

Jane Jackson, widow, on coming into court, refused to be

sworn until Dr. Moore was present. Her objection being overruled by the coroner, she deposed that deceased was her husband; that he had been complaining of a cold since early in November, 1850; that in the latter end of January he left home for the purpose of consulting Dr. Taylor, who prescribed for him some medicine, with directions to be divided into fifteen papers, which disagreed with him; some time in February again visited Dr. Taylor in company with deceased, when the doctor examined his breast and back with an instrument, and told him he was seriously affected, and that he might die suddenly; at this time he prescribed a box of pills containing twenty-one, one to be taken three times in the day, and to have boiling water and milk for drink; he took eleven of the pills, which poisoned him; no restraint of diet; I burnt the remainder of the pills, which I now regret, having lost the opportunity of having them analysed; I visited Dr. Taylor in the month of March, and told him deceased's mouth was sore; the doctor said it would do him good, and to get an alum wash, which I did, but did not use it; on my return home, sent for Dr. Moore, who visited him same day, and sent him medicine, and was in attendance on him up to his death with good effect.

On cross-examination, stated that Dr. Taylor has been in attendance on deceased and family for the last twenty-five years, and had the greatest faith in him up to the time of his mouth getting sore; whilst using the powders left home occasionally, and was absent two nights twenty miles distant.

(Copy) JANE JACKSON.

Anne Jackson, daughter, deposeth—That deceased was my father, and lived with him during his illness; he told me repeatedly that Dr. Taylor's medicine had destroyed him, for it was mercury; was visited by Dr. Moore, who told him he had been taking mercury; my father said he was not; the doctor said he was, for he felt the smell, and that he had got as much as would kill a horse without directions to take care of himself; also deposeth that on Monday, the 2nd of June, after being visited by the coroner, who took our joint informations, I left home for Bailieborough, and went to Dr. Moore's house, where I met my uncle and Dr. Moore, and remained for a considerable time.

On cross-examination, refused to relate the conversation that took place there. (Copy) ANNE JACKSON.

Mark Moore, Surgeon, Bailieborough, deposeth—That I was in attendance on deceased since March last; when I first saw him, he was labouring under extreme difficulty of breathing, which incapacitated him from lying down; saw some pills in his house which he told me he had been taking, but cannot say what was their composition; I attended him up to his death, and prescribed for him; he laboured under disease of his kidneys, the symptoms of which are, great difficulty of breathing, irritability of stomach, frequent wandering in his mind, and spasms of the extremities; his urine on being boiled, threw down a copious precipitate of albumen, its specific gravity from 1008 to 1012; I am of opinion that he died from disease of his kidney.

On cross-examination, admitted that on his first visit told deceased that he had taken mercury, and that it was a shame for Dr. Taylor to have given you so strong medicine without proper direction to take care of yourself.

(Copy) MARK MOORE, Surgeon.

Bernard Coyne of Cavan, Surgeon, deposeth—That I have examined the body of deceased, which was exhumed this day; decomposition has set in to a considerable extent; there is œdema of the lower extremities; on opening the abdomen, found all the fixed viscera healthy, except the left kidney, which was a mass of disease of long standing from repeated attacks of inflammation; on opening the chest, found the lungs rather healthy, but the chief organ that attracted my attention was the heart, which occupied most unusual space from its enlargement from hypertrophy and thickening of its walls; the pericardium contained three times its usual quantity of fluid; I am of opinion that he died from disease of his heart and kidney, either of which was sufficient to have killed him; I have examined the prescriptions written for the deceased by Dr. Taylor, who declares on oath they are the genuine ones, and am of opinion they were judicious, and could not produce any bad consequences.

(Copy) BERNARD COYNE, Surgeon.

Verdict.—"Died from disease of the heart and kidneys on the 19th of May, 1851; and we do acquit Dr. Taylor of having given him any injurious medicine that would tend to increase the disease of which he died, as was alleged."

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, JULY 9, 1851.

THE first act of the medico-political drama, which has been for some years in preparation, was performed on Friday last, in no less elevated a locality than the Council Chamber of Dublin Castle, and under no less elevated than viceregal auspices. It has been our fortune, good or bad, to witness strange occurrences in our time, but never did we dream of witnessing such a sight as the usurpation of the functions of a medical faculty by the Queen's representative and his councillors. So it is, however; there they met in solemn state to decide upon the merits of persons proposing to examine medical students; and then and there did the Lord Lieutenant, the judges of the land, and heads of departments, decide upon the fitness of doctors, surgeons, and midwives. It is literally so, as appears from the following official bulletin:—

At a meeting of the Senate of the Queen's University for Ireland, held in the Council Chamber, Dublin Castle, on yesterday, the following candidates for the office of examiners were duly elected:—

Cathcart Lees, M.D., in the Theory and Practice of Medicine.

John Hamilton, M.D., in Surgery.

H. Carlisle, M.D., of Belfast, in Anatomy, Physiology, and Comparative Anatomy.

James Apjohn, M.D., in Chemistry.

Alexander Fleming, M.D., of Cork, in Materia Medica, Pharmacy, and Medical Jurisprudence.

George J. Allman, M.D., in Zoology and Botany.

Thomas M'Keever, M.D, in Midwifery and the Diseases of Women and Children.

Sundry judges and other lawyers, a captain of engineers, a Presbyterian clergyman, a doctor, a surgeon, and a civil engineer, thus decide on the qualifications of those who are to decide on the qualifications of the future members of our profession. It is no business of ours to question the decision come to; all we want is to make known the true character of these proceedings, and to prepare our brethren for what is to follow. As far as we have been able to ascertain, there were some thirty candidates, or more, for these seven offices, the majority of them having high claims, and the above is the result. But the truth is, that the whole affair is little better than a barefaced hoax, as regards our profession—a mere manœuvre to take the wind out of the Pope's sails, and get the weather-guage of the other new university. The provincial college people admit that they have no pupils ready, or honestly qualified, to offer for these mock degrees, and every one amongst us knows that no one else is thinking of them. Indeed, few are troubling their heads about any medical degrees. Eight or ten only graduated this year in Trinity College, and as many more from Ireland may take degrees in Edinburgh; but the trade in these parchments is all but extinct. The surgeon is now content with his legitimate title and diploma, and has no money to spare for another, which is but a fictitious copy of it. As long as the medical colleges were devoted to the education of physicians and the granting of true medical degrees, surgeons sought their diplomas as an additional qualification; but since they have been obliged to resort to a patching-up of their tottering fabrics with surgical materials, the value of the parchment has declined. We are aware that great efforts are making, after maul-em-in fashion, to "draw"

candidates for these Castle degrees, and we shall not be surprised to find "exhibitions" provided for those who take them; but as surely as we write this, there is not one medical man in the whole country who does not know well that the whole affair is a rank job from beginning to end. It seems to be admitted on all hands that the number of candidates for these diplomas cannot exceed ten, if they even approach that number, and so, we have some five or six hundred pounds of public money expended to dub half a score of apothecaries' boys, who, if left to themselves, would not have cost the country a farthing. With grand political manœuvres we have nothing to do, and care not how far the machinery of patronage may be put in motion to manufacture sops for Cerberus, or tubs for whales; all we have to attend to are the attempts to make medical men scapegoats in these paltry intrigues, and to that we are determined to apply ourselves. The entire body of our profession, from one end of the country to the other—from metropolis to village—is thrown into a state of confusion, apprehension, and uproar, by a combination of place-making, place-hunting, and corrupting proceedings, which contemplate the disruption of all-existing institutions, and the substitution of a concentrated system of red-tape government, commencing with bribery, and to end in oppression and degradation. This is a state of things we will not tamely submit to, and therefore do we, on this day, give notice of our determination to provide a remedy for it, which, if it does not prove successful in the sequel, will prove that no method has been neglected which promised to counteract such doings.

MORE OFFICIAL PARAGRAPH PUFFING.

At the moment when all men are pondering upon the calamities which the present census reveals, the following is the use to which a government official applies the documents which announce the results. This, and other similar minglings of private interests with public duties, has become a crying scandal, and, we do not hesitate to say, is calculated to bring the government of the country into contempt:—

Without paying a tribute, however brief and inadequate, to the commissioners for the in every way satisfactory manner in which they have executed their gigantic task, to Dr. Wilde, particularly, we are aware a large amount of thankfulness is due for the untiring perseverance with which the huge bodies of details were classified, and for the clear and satisfactory fashion in which they will be presented to the public. Aware, as we had been, that to Mr. Wilde we are indebted for those very important vital statistics and valuable tables of Irish diseases, which formed a distinguishing feature of the last census, we, of course, could not have expected any other result than that which has attended his present labours. We, however, may take the opportunity, differing, though we do, from the general policy of the Irish executive, of acknowledging, frankly and unreservedly, the wisdom and justice shown by Lord Clarendon in the selection of a commissioner in every way so competent as Dr. Wilde. It is but justice to say that we are indebted to *Saunders's News-Letter* for being enabled to give this evening the Abstract of the Census, which has called forth these remarks.

What will Mr. Donnelly and Mr. Singleton, the persons really entitled to the entire credit of doing this work, say to this? If these "huge bodies of details were classified" by the "untiring perseverance," after so clear and satisfactory fashion," by Dr. Wild, how comes it that the country is to be saddled with the expense of other "heads" in the same department? But what are we to think of the discipline of the public offices of Dublin which permits common working subalterns to thus publicly set up a claim for credit due to their superiors. A person in authority may, for reasons best known to himself, dub the *pro tem. locum tenens* of a subordinate office a "commissioner," but surely that stretch of authority did not authorize such a person to go himself a step higher. By the way, it is somewhat amusing to see the "commissioner," since we last noticed this affair, reduced to the rank of "assistant-commissioner," and, still more, his laudable anxiety to be considered "*a doctor.*" We have not, however, been able to find his name in any list of graduates of any college in England, Ireland, or Scotland, and, therefore, do we conclude that his medical honours are derived from some higher source. Of the value of whatever pertains to medical science in the report of this census, some opinion may be formed from these public displays. Statements of facts, prefaced by such flourish of trumpets, are not very likely to have much weight with sober men; and certain, therefore, are we that these "vital statistics" will follow their predecessors to the snuff-shop, notwithstanding "the wisdom and justice shown by Lord Clarendon in selecting a commissioner in every way so competent as Dr. Wild."

HOUSE OF COMMONS—Wednesday, July 2.

MEDICAL CHARITIES (IRELAND) BILL.

The house went into committee on this bill, and clause 2 was agreed to.

On clause 3, relating to the appointment of inspectors,

Lord Naas moved, as an amendment, that they should be "practising" physicians or surgeons of not less than ten years' standing.

For the amendment	51
Against it	44
Majority	—7

The clause, as amended, and clauses 4 and 5, were agreed to.

On the 6th clause, which was to enable guardians of unions to divide them into dispensary districts,

Mr. H. Herbert moved, as an amendment, the omission of all the words in the clause after those which enabled the guardians to make such division, if the poor-law commissioners approved thereof, and the insertion in their place of words giving a power of appeal to the Lord Lieutenant in Council

Sir W. Somerville considered the appeal was unnecessary.

Mr. Hatchell opposed the amendment, on the ground that it would embarrass the operation of the bill.

Mr. Wakley, in supporting the amendment, observed that he had seen the condition of Ireland last year, and he considered that such a measure as this was a complete farce. He could state, from his own observation, that in districts through which he passed the people were dying for want of food, or from disease produced by starvation. The medical officers of districts were not empowered to order relief for the people in the shape of food; but here was a measure to give them as much jalap and Epsom salts as they wanted! The fact was, that the bill did not give medical men any power to order such food as might be requisite for the sick poor; and he did not think, therefore, that it would be attended with any practical benefit. He had been told last year by a guardian of the poor in Ireland that in the previous summer, between the 18th of June and the 3rd of October, 1100 persons perished in the workhouse at Listowel (as we understood), and that they were nearly all taken into the house in a dying state from starvation. He thought, therefore, that medical officers should have the power of ordering food and nourishment for the people when they thought it necessary.

After some conversation, the committee divided, when there were—

For the amendment	58
Against it	70
Majority against the amendment ...	—12

Lord Naas then proposed to insert the words "on application from the board of guardians," in that portion of the clause which provides that the commissioners may, from time to time, alter the dispensary districts.

A short conversation followed, the result of which we understood to be that the government would not object to the insertion of words, to be prepared before the report, giving the initiative to the guardians, with power to the commissioners to vary the proposal of the guardians if not approved of.

Mr. H. Herbert moved to strike out the words "number and" from that part of the clause which provides that the commissioners shall declare "the number and qualifications of the officers to be appointed for the service of each dispensary district." This was taking all control from the owners of property.

Mr. Grattan could not pity Irish gentlemen; they were superseded, but they deserved it. Where were those who ought to be taking care of the poor? Spending their money at the Exhibition (a laugh). Legislation was driving the Irish gentlemen out of their country; the bone and sinew of the nation were being taken out of it. Let any one read the report of the Emigration Commissioners. Ireland was being reduced to such a state that you would not find a gentleman to live there in a few years—you would have a mob there kept down by an army.

Sir W. Somerville, in reference to the particular question before the committee, would observe that the regulation objected to was in force now under the poor-law. He did not see how a better or safer arrangement could be made.

Lord Naas did not consider the poor-law analogous; under this bill the salaries of the medical officers and expense of management would form the whole expenditure.

Colonel Dunne was in favour of local management of these institutions.

Sir J. Young thought it safer and more economical that the power of fixing the number should be vested in the commissioners rather than in the local authorities. The interests both of the ratepayers and of the sick would be better consulted.

The committee divided. The numbers were—

For the amendment	44
Against it	57
Majority	—13

The Chairman then reported progress.

MEDICAL CHARITIES' BILL FUND.

The following subscriptions have been received, in addition to those already acknowledged:—

Dr. J. Clarke, Emo, Queen's County; Dr. J. Cronin, Erril, Queen's County.

Newry, July 6, 1851. J. Morrison, Treasurer.

Hydrocephalus,	24	Childbirth,	4
Apoplexy,	19	Uterus,	3

INSTRUMENT FOR APPLYING ELECTRIC HEAT IN DENTAL OPERATIONS.

I use Grove's battery with eight cells. When using it I have in my hand a holder with two copper wires passing through it—one positive from the battery, and the other terminating in a groove in the holder and fastened to a spring, by which I make or break contact at will with the negative wire. To the further end of the two wires a thin platinum wire is connected, and on the battery being charged and contact made, this takes suddenly the electric heat. The efficacy and simplicity of the process being so decided, I am enabled to use it for many purposes—viz., to evaporate quicksilver from cements, and render them much less injurious to teeth than they otherwise would be; also where too great sensitiveness exists, and which prevents the operator from removing the caries; where gums have receded and left the necks of teeth highly sensitive to the touch; where teeth are affected by mollities which cannot by other means be combated; where teeth have to be pivoted, and when vitality remaining in the root would subject the patient to serious inflammation; where teeth have been broken, or cut, or filed, and left sensitive to cold and warmth; where violent toothache exists; where hæmorrhages come on, or slight bleeding into the cavity, preventing a continuance of any operation.

The electric heat retains its force differently to all other heat which can be applied to the mouth; the platinum wire can be placed, without the patient being aware of it, near the part affected, heat can be produced almost momentarily, and suddenly deadened, and as a most interesting phenomenon, and one which has surprised me very much, in patients of a highly nervous temperament where I have expected much suffering, none has been endured on its application. It would be superfluous here to detail many interesting facts which the use of electric heat will discover to the scientific dentist; these philosophy explains with the laws of the sensitive faculty. It is my sincere hope that operators will be judicious in the use of this agent, and not bring it into disrepute by ill-judged and ill-timed applications. In many cases it will be found equally efficacious when holding it near the teeth, as if they were touched by it. Care must be taken not to continue in its application too long, as it will burn up and blacken the part it touches.

As time passes on, I look forward to its use being generally understood, and it will then give rise to many improvements tending to the benefit of society.—*Mr. Waite, Surgeon-Dentist, in Lancet.*

UNIVERSITY OF LONDON.

NOTICE is hereby given, that the FIRST EXAMINATION for the Degree of BACHELOR of MEDICINE, for the present year, will commence on MONDAY, the 4th of August.

The Certificates required must be transmitted to the Registrar fourteen days before the commencement of the Examination.

By order of the Senate,
R. W. ROTHMAN, Registrar.
Somerset House, June 27, 1851.

ROYAL COLLEGE OF SURGEONS.

THE Professors of Anatomy will appoint a Demonstrator on MONDAY, July 14th. Candidates for the office should transmit their proofs of qualification, one week at least before the day of election, under cover to Mr. BOYLAN, the Registrar at the College.

THE MIDLAND RETREAT,
(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY,)
For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System.
Under the direction of Dr. JACOB,
Physician to the Maryborough District Lunatic Asylum, (containing 200 patients,) Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

DISPENSING OF MEDICINE.

G. OLDHAM AND CO.,
PHARMACEUTICAL CHEMISTS, AND APOTHECARIES,
From BEWLEY and EVANS',
No. 107, GRAFTON-STREET, DUBLIN,
(Corner of Suffolk-street),

BEG to return their grateful acknowledgments to the Medical Profession for the support they have hitherto received, and which they will regard as a fresh motive for exertion. Abstaining altogether from visiting as Apothecaries, except for the application of Leeches, Cupping, and such operations as are performed under medical advice, they will continue to devote themselves exclusively to the duties devolving on the pure Pharmacien.

Having had much experience in Practical Pharmacy, and being resolved to spare neither trouble nor expense in order to have every article of superior quality, they hope by attention, "carefulness," punctuality, and moderation of charges, to commend themselves to the approbation of those who may entrust them with their commands.

☞ *G. O. and Co. invite attention to their present stock of Surgical Instruments, all of which are manufactured on the most modern and improved principles.*

BRAITHWAITE'S RETROSPECT OF MEDICINE.

Just published, price 6s., cloth, Vol. XXIII.—January to June, 1851,

GIVING a careful Analysis of the most Practical Papers, Lectures, and Transactions of Societies, published in all the Medical Journals within the last Six Months. Appended to which is an Alphabetical List of Diseases; with the most recent Suggestions of Treatment.

Edited by W. BRAITHWAITE,
Lecturer on Obstetric Medicine in the Leeds School of Medicine, &c.

London: Simpkin, Marshall, and Co.: Edinburgh: Oliver and Boyd. Dublin: Hodges and Smith.

ON CATARACT OR OPACITIES OF THE CRYSTALLINE LENS.

By Arthur Jacob, M.D., F.R.C.S.,

Professor of Anatomy and Physiology in the Royal College of Surgeons in Ireland, and Surgeon to the City of Dublin Hospital.

(Continued from p. 21.)

I have said that the lens consists of an outer case or capsule totally different from the solid body contained within it. This capsule is strong, elastic, and perfectly transparent. In the paper to which I have alluded in the Medico-Chirurgical Transactions, I gave the following detailed description of its nature and properties:—"The real nature of the capsule of the lens has not, I think, been sufficiently attended to; its thickness, strength, and elasticity have certainly been noticed, but have not attracted that attention which a fact so interesting, both in a physiological and pathological point of view, deserves. That its structure is cartilaginous, I should conclude—first, from its elasticity, which causes it to assume a peculiar appearance when the lens has been removed, not falling loose into folds as other membranes, but coiled in different directions: or if the lens be removed by opening the capsule behind, and withdrawing it through the vitreous humour, allowing the water in which the part is immersed to replace the lens, the capsule preserves in a great degree its original form, especially in the eye of the fish; secondly, from the density and firmness of its texture, which may be ascertained by attempting to wound it by a cataract needle, by cutting it upon a solid body, or compressing it between the teeth; thirdly, from its permanent transparency, which it does not lose except on the application of very strong acid or boiling water, and then only in a slight degree; maceration in water for some months, or immersion in spirit of strength sufficient to preserve anatomical preparations, having little or no effect upon it. If the lens be removed from the eye of a fish dressed for the table, the capsule may be raised by the point of a pin, and be still found almost perfectly transparent. This combination of density and transparency gives the capsule a peculiar sparkling appearance in water, in consequence of the reflection of light from its surface, resembling a portion of thin glass which had assumed an irregular form while soft; this sparkling I consider very characteristic of this structure. The properties just enumerated appear to me to distinguish it from every other texture but cartilage; still, however, it may be said that cartilage is not transparent, but even the cartilage of the joints is semitransparent, and if divided into very thin portions, is sufficiently pellucid to permit the perception of dark objects placed behind it, and we obtain it almost perfectly transparent where it gives form to the globe of the eye, as in the sclerotic of birds and fishes. If the soft consistence, almost approaching to fluidity, of the external part of the lens, be considered, the necessity of a capsule capable itself of preserving a determinate form is obvious. If the lens were enclosed in a capsule such as that which envelopes the vitreous humour, its surface could not be expected to present the necessary regular and permanent curvature; nor could we expect that if the form of the lens were changed, it could be restored without this provision of an elastic capsule."

The capsule is liable to become opaque and constitute cataract, as the body of the lens is. These capsular cataracts are easily distinguished from the lenticular. They never present the stellated appearance frequently observed when the texture of the opaque lens opens in the capsule as it does when macerated in water, nor the uniform horny or the milky blue appearance of common lenticular cataract. The opacity in capsular cataract exists in the shape of irregular dots or patches, of an opaque paper-white appearance, and when touched with the needle are found hard and elastic, like indurated cartilage, the spaces between the specks of opacity frequently remaining perfectly transparent.

It appears to be generally assumed by writers on anatomy that a watery fluid is interposed between the body of the lens and its capsule, from an incidental observation of Morgagni when discussing the difference in density between the surface and centre of the lens; hence it has been called

the *aqua Morgagni*. The observation of this celebrated anatomist, in his Adversaria Anatomica, which has led to the universal adoption of this notion, is, however, merely that upon opening the capsule he had frequently found a fluid to escape. "Deinde eâdem tunicâ in vitulis etiam, bobusque sive recens, sive non ita recens occisis perforata, pluries animadverti, illico humorem quendam aqueum prodire: quod et in homine observare visus sum, atque adeo credidi, hujus humoris secretione prohibitâ, crystallinum siccum, et opacum fieri ferè ut in extracto exsiccatoque crystallino contingit." He does not, however, subsequently dwell upon or insist upon the point. I do not believe that any such fluid exists in a natural state, but that its accumulation is a consequence of loss of vitality; the water combined with the solid parts of the lens escaping to the surface and being detained by the capsule, as occurs in the pericardium and other parts of the body. In the eyes of sheep and oxen, when examined a few hours after death, not a trace of any such fluid can be detected, but after about twenty-four hours it is found in considerable quantity. In the human eye a fluid sometimes accumulates in the capsule, constituting a particular form of cataract, which presses against the iris, and almost touches the cornea; but such eyes are, I believe, always unsound. From this erroneous notion of an interposed fluid between the lens and its capsule has arisen the adoption of an unsustained and improbable conclusion, that the lens has no vital connexion with its capsule, and consequently must be produced and preserved by some process analogous to secretion. Respecting this matter I have observed, in the paper above alluded to: "The lens has been considered by some as having no connexion with its capsule, and consequently that its formation and growth is accomplished without the assistance of vessels; such a notion is so completely at variance with the known laws of the animal economy, that we are justified in rejecting it, unless supported by unquestionable proof. The only reasons which have been advanced in support of this conclusion are, the failure of attempts to inject its vessels, and the ease with which it may be separated from its capsule when that membrane is opened. These reasons are far from being satisfactory; it does not necessarily follow that parts do not contain vessels, because we cannot inject them; we frequently fail when there can be no doubt of their existence, especially where they do not carry red blood. I have not myself succeeded in injecting the vessels of the lens, but I have not repeated the trial so often as to make me despair of accomplishing it, more especially as Albinus, an anatomist whose accuracy is universally acknowledged, asserts, that after a successful injection of the capsule of the lens, he could see a vessel passing into the centre of the lens itself. Lobé, who was his pupil, bears testimony to this. The assertion that the lens is not connected with its capsule, I think I can show to be incorrect; it has been made from want of care in pursuing the investigation, and from a notion that a fluid exists throughout between the lens and its capsule. When the capsule is opened, its elasticity causes it to separate from the lens; especially if the eye be examined some days after death, or has been kept in water, as then the lens swells, and often even bursts the capsule and protrudes through the opening, by which the connexion is destroyed. I have, however, satisfied myself that the lens is connected with its capsule (and that connexion by no means slight) by the following method. I remove the cornea and iris from an eye, within a few hours after death, and place it in water, then with a pair of sharp-pointed scissors I divide the capsule all round at the circumference of the lens, taking care that the division is made behind the anterior convexity, so that the lens cannot be retained by any portion of the capsule supporting it in front. I next invert the eye, holding it by the optic nerve, when I find that the lens cannot be displaced by agitation, if the eye be sufficiently fresh. In the eye of a young man about six hours dead, I found that, on pushing a cataract needle into the lens, after the anterior part of the capsule had been removed, I could raise the eye from the bottom of the vessel, and even half way out of the water, by the connexion between the lens and its capsule. It afterwards required considerable force to separate them, by passing the needle beneath the lens, and raising it from its situation. I believe those who have been in the habit of performing the operation of extraction, have occasionally encountered considerable difficulty in detaching the lens from its situation after the capsule had been freely opened, this difficulty I consider fairly referrible to the natural connexion just noticed." When the lens enclosed in its capsule is detached from the hyaloid membrane, the connexion between it and the capsule is destroyed by the handling, and in consequence, it moves freely within that covering, affording to those who believe that there is no union between the two surfaces fallacious evidence in support of that opinion, which, if not sustained by better proof, should be abandoned. Dr. Young insists upon the existence of the natural connexion by vessels and even by nerves between the lens and its capsule: he says—"The capsule adheres to the ciliary substance, and the lens to the capsule, principally in two or three points; but I confess I have not been able to observe that these points are exactly opposite to the trunks of nerves; so that probably the adhesion is chiefly caused by those vessels which are sometimes seen passing to the capsule in injected eyes. We may, however, discover ramifications from some of these points upon and within the substance of the lens, generally following a direction near to that of the fibres, and sometimes proceeding from a point opposite to one of the radiating lines of the same surface. But the principal vessels of the lens appear to be derived from the central artery, by two or three branches at some little distance from the posterior vortex, which I conceive to be the cause of the frequent adhesion of a portion of a cataract to the capsule about this point; they follow nearly the course of the radiations and then of the fibres; but there is often a superficial subdivision of one of the radii at the spot where one of them enters." The great size of the vessels distributed on the back of the capsule in the fœtus strengthens the conclusion that the lens is furnished with vessels as the rest of the body. When the eye of a fœtus of seven or eight months is finely injected, a branch from the central artery of the retina is filled and may be traced through the centre of the vitreous humour to the back of the capsule, where it ramifies in a remarkably beautiful manner, assuming, according to Sömmerring, a stellated or radiating arrangement. Zinn declares that he found branches from this vessel penetrating the lens: "Optime autem placet observatio arteriolæ lentis, in oculo infantis, cujus vasa cera optime erant repleta, summa voluptate mihi visæ, quam prope marginem ad convexitatem posteriorem dilatam, duobus ramulis perforata capsula in ipsam substantiam lentis profunde se immergentem cortissime conspexi." He also quotes the authority of Ruysch, Moeller, Albinus,

and Winslow, as favouring the same view. Against such authority I find that of the French systematic writer Bichat advanced; but on such a point his opinion is of little value.

ON CATARACT OR OPACITIES OF THE LENS.

Having endeavoured to explain the form, properties, organization, and vitality of the lens, I have now to consider the changes it undergoes from age, inflammation, imperfect or irregular nutrition, and injury. Writers on ophthalmic surgery enumerate a great variety of cataracts, applying different names to every different appearance which these opacities assume, as they have done with respect to opacities of the cornea. This, however, is of little use, causes unnecessary trouble and confusion, and diverts the mind from the investigation of the real cause of these appearances. It is much better to consider the real nature of these changes, and to explain the state of structure belonging to them. The crystalline lens does not become opaque from a great number of different diseases affecting it; it is only the forms of opacity which are so numerous. In the first place, it must be obvious that the lens being composed of two structures so different in every respect as the capsule and the body of it, and that both these being liable to become opaque, there must necessarily be at least two very different forms of opacity, and hence the division of cataracts into capsular and lenticular. The lenticular is to be first noticed. From what has already been said respecting the change which the lens undergoes in advanced life, it is clear that it is liable to become still more changed from the same cause, and experience has proved that such is the case. In the great majority, it not only becomes much more flat, and hence long sight requiring convex glasses, but also coloured, acquiring an amber tint, although previously clear as water. In still more advanced life it also loses its perfect transparency, and becomes slightly opaque or milky, although not so much so as to impair vision materially. This I conclude from the appearance it presents on dissection, and when seen in the living subject by causing the light to be reflected from it, especially when the pupil is dilated with belladonna. When this colour and loss of transparency increase still more, vision becomes impaired and the opacity becomes visible in the pupil, constituting the lenticular cataract of advanced life, one of the most common forms of the disease met with. But the lens at this period becomes not only coloured and milky or opaline, but also much firmer in consistence, and hence the hardness of this species of cataract. The appearance, however, of the hard lenticular cataract of advanced life varies very much. It generally resembles a piece of muddy amber, or still more, common horn, such as is used for lanterns; but is sometimes so brown that it cannot be seen behind the pupil unless a strong light be thrown on it obliquely, and hence probably the origin of the notion that there is a black cataract. The hard lenticular cataract frequently also presents the appearance which has been denominated glaucoma, a greenish shining hue not easily described, and scarcely to be represented in a drawing. This semitransparent, amber, horny or opaline state of the lens is not, however, by any means the uniform appearance of the lenticular cataract of advanced life; on the contrary, the cataract of old persons is often of an opaque white, or even a bluish white, like the lenticular cataract of early life, or it may be irregularly clouded, stellated, or combined with capsular cataract.

The stellated opacity of the lens which sometimes occurs in the lenticular cataract of old age, but more frequently in that of earlier life, it is necessary to consider distinctly, because it is the result of additional disorganization, and indicates a softer state of the lens, rendering it more easily broken up and more fit to be absorbed. I have already shown that from its fibrous structure, the lens splits up into segments when immersed in water or other fluid, and from whatever cause it may be, a similar change sometimes takes place during life, constituting this stellated opacity or cataract. There is no difficulty in recognizing this state, or of perceiving that it depends upon a yielding of the natural structure, and that it is accompanied by a corresponding softness and looseness of texture favourable to division with the needle. This splitting up of the lens into segments, from the centre to the circumference, may be produced by removing it from the eye of a sheep or other animal enclosed in its capsule, and leaving it in water for a day or two. Thus treated it becomes opaque, while the bars of the stellated breach on its anterior surface are transparent, being in fact filled with water. Now, if we are to give a name to these different states, we may call the uniform amber or horny opacity the hard amber or horny cataract of advanced life; and if marked by bars radiating from the centre to the circumference, we may add that it is stellated.

There is, however, another kind of opacity which occurs at an advanced period of life which presents a more or less stellated arrangement. This is produced by delicate slender white streaks which run in the direction of the fibres, and therefore from centre to circumference, the rest of the lens retaining its transparency, or being only slightly opaque; so much so, that persons with this kind of cataract often enjoy useful vision. These white streaks or veins do not, however, always or even frequently assume the stellated arrangement, but run as single streaks across the whole face of the lens, with perhaps one or two other streaks diverging from it about the centre. It is a remarkable, distinct, and easily recognized opacity, although it often escapes notice, especially where the pupil is small; and is obviously very different in its nature from the hard, amber, or horny cataract just described. It is also remarkable for the slowness of its progress to perfect opacity, often existing for many years before it causes blindness and requires operation. Such cataracts are not, perhaps, harder than a healthy lens at the same period of life, and the streaks of opacity are obviously not slits or spaces formed by the receding of the fibres from each other, but an induration and consequent opacity of a certain number of them, the rest remaining transparent. I am surprised that this form of cataract has not been more particularly described and distinguished from the common hard stellated cataract, especially considering the anxiety shown to multiply varieties and vary names, for there can be no doubt of its being of a peculiar nature. It is it Mr. Mackenzie alludes to when he says—"It is not an uncommon appearance to see opaque *striæ* stretching from the circumference of the lens a short way into its substance;" and Mr. Lawrence notices it as a radiated cataract having the rays commencing at the circumference instead of at the centre, as in the more common or softer stellate cataract. "Lenticular cataracts (he says) are sometimes *radiated*, the opacity appearing in streaks or *radii*, with the intervals comparatively transparent. Those radii generally begin in the circumference of the lens—a circumstance which forms a striking contrast to the former species, in which the opacity

first appears in the centre. In the ordinary state of the pupil we can hardly see the radiated opacity, because the centre remains transparent; perhaps a small white streak or two may be distinguished: it is not, however, till we have dilated the pupil by belladonna that we detect the opaque streaks in the circumference of the lens." I sometimes, however, find these opaque striæ in the lens without the marginal radii. Of the hard lenticular cataracts of advanced life, we have then the amber or horny, the stellate, and the striated, but these are not the only varieties.

Cataracts in old persons are often white and very opaque without any *radii*, presenting a muddy cream-coloured or even a bluish milky uniform surface, behind the pupil, and such often have an opaline lustre from a hard amber central nucleus reflecting the light through a semitransparent superficial stratum. These cataracts appear so soft and pulpy that they often tempt persons to operate on them with the needle to cause their solution and absorption, but they are almost always hard in the centre, leaving a small nucleus undissolved for a very long time in the posterior chamber after operation, moving up and down with the motions of the eye. Besides these four distinct forms of hard lenticular cataract of advanced life, the amber, stellated, striated, and white or opaline, there are many intermediate varieties which might be enumerated under different names, and also many rarer varieties of the same species presenting such peculiarities that they might be described very properly as peculiar products of disease; but my object is to direct attention to the usual forms with a view to ascertain their consistence and solubility for the purpose of determining which operation should be chosen for their removal. It should, however, be observed that all these lenticular cataracts are more transparent and softer at the circumference, because the lens in health is there thinner and softer, and consequently, that when the pupil is dilated with belladonna, they admit more light and appear less opaque at the margin, except indeed it be the striated cataracts which are often more opaque at the circumference.

Lenticular cataracts are not found in persons advanced in life only, they occur at every period from infancy to old age, but in early life they are very different in form, consistence, and colour. As the hard amber cataract is that which occurs most frequently in aged people, the light-blue or milky one generally constitutes the disease in younger persons. It is also much softer, frequently indeed softer than the lens is in its natural or healthy state at the same period of life; and instead of being shrunk or flat, it is generally enlarged or swelled. Therefore, as has been said, the hard amber-coloured shrunk lens most commonly forms the cataract of advanced life, while the soft milky-blue prominent one is found most frequently in early life. There are, however, many varieties and modifications of the disease at this period, as there are at the other. Of these varieties, that which most frequently occurs is the starred or stellated one already noticed as a variety of the harder cataract of advanced life: the lens, in fact, being not only opaque, but so disorganized or changed in structure, that it has split up on its surface and exhibits deep fissures radiating from the centre to the circumference. The colour, however, instead of being a dirty-white, as in old age, is a milky-blue, and the fissures are of a lighter tint, as if filled by water, which they probably really are, the whole being so soft and pulpy that there is no difficulty in completely mashing it up with the needle in operation. A variety of the striated cataract described as occurring in advanced life, is also often found in early life, the striæ commencing at the circumference and converging to the centre, and not being open fissures but opaque veins with transparent intervals between them. Sometimes a defined circular white spot, very opaque, is found occupying the centre of a transparent lens, with one or more equally opaque thick bars or veins radiating from it toward the circumference. In using the term vein, I mean veins such as exist in minerals. This central opacity with dense radiating striæ, is generally, but not always, accompanied by an equally dense defined opacity of the capsule of smaller size, easily distinguished by its chalky whiteness and cartilaginous appearance, constituting a variety of capsulo-lenticular cataract. This dense opacity of the lens has not, however, always the bars or striæ radiating to the edge, but exists alone in a lens perfectly transparent to the circumference, admitting of very useful vision when the pupil is dilated with belladonna. Such are very slow in progress, sometimes, in fact, being permanent, and undergoing little or no change for many years, if not indeed for life, and they are often congenital, but I think not always, for I have sometimes found them in persons somewhat advanced in life who insisted upon it that they had always had good sight until a comparatively recent period. The late Mr. Tyrrel, in his book on Diseases of the Eye, describes the striated cataract, but does not, I think, appear to have distinguished it from the stellated. He says, alluding to the distortion or multiplication of objects in incipient cataract, "when these modifications of symptoms have presented themselves, I have found that the opacity of the lens has not been confined merely to the centre, but that one or two, or several, opaque radii have existed, passing from the centre to the circumference of the body." (Vol. ii., p. 355.) And again (p. 363), "In rare instances, when cataract commences from the circumference, and proceeds by radii toward the centre, these radii are at first confined to the posterior hemisphere of the lens. This opinion, however, is equally erroneous with that before adverted to respecting the anterior portion of the lens, as I have had opportunity of ascertaining by watching the progress of such cases, and subsequently extracting the cataracts." Mr. Saunders in his treatise (p. 133., pl. iv., fig. 3,) says:—"There is a form of the congenital cataract in which the centre of the lens is opaque and its circumference perfectly transparent. In these cases the lens remains of its natural size as long as its circumference preserves its transparency, which, if undisturbed, it will do for many years." Fig. 3, referred to, shows, he says, "a lens of which the centre is opaque and the circumference is transparent, with the exception of *three opaque radiated lines*;" and it shows also a small defined opacity of the capsule over that of the lens, but smaller than it. I have now in this paragraph shown, that of the lenticular cataract of earlier life there are four varieties: the uniform light-blue or milky; the stellated, or split from centre to circumference; the radiated, with veins from the edge toward the centre; and that with an opacity in the centre, with or without white bars or thick veins running to the edge. But these are not all, for sometimes the opacity is irregularly clouded, as if the original fibrous structure of the lens was destroyed, and the part converted into a grumous mass, as it appears some weeks after having been freely broken up by the needle. Mr. Wardrop, in his essays on the Morbid Anatomy of the Eye (vol. ii., p. 81), says, alluding to this variety:—

"Sometimes they are clouded in different parts, having the appearance of a flake of snow;" and Mr. Tyrrel (vol. ii., p. 364) says:—"Sometimes the surface of the opaque body appears flocculent, like the surface of a recently broken piece of spermaceti." These cataracts are very soft, and are speedily absorbed after breaking up. If they are to have a name, they may be called flocculent. There is yet another variety which I have often seen and operated on. It is a very light-blue cataract, the colour of milk and water, which evidently contains a quantity of fluid between the lens and its capsule, for it is quite prominent, pressing upon the iris so as to cause dilatation of the pupil, and almost, if not all out, touching the back of the cornea. This can be distinctly seen by looking at the eye in profile, or sideways, the patient facing the light. Before I was aware of the existence of this form of cataract, I was much surprised to find that in operating on it I did not break it up and scatter the pulp into the anterior chamber, as I do in very soft cataracts, but that the more I worked at it the less it moved. In fact, I had been all the time moving the needle about within the capsule, but when I saw how it was circumstanced I brought the instrument up to the back of the cornea and tore open the capsule, when it was immediately mixed up with the aqueous humour as usual. Whether or not it is this variety which authors allude to under the name of Morgagnian cataract I cannot tell, because they seem to differ in their descriptions of it. Mr. Mackenzie, in his work on Diseases of the Eye, appears to describe it under this title. He says:—"The effusion of an opaque fluid between the lens and its capsule forms one of the rarest kinds of cataract. It is generally followed by dissolution of the lens, and not unfrequently by capsular opacity. So long as the cataract consists in a mere effusion between the capsule and lens, it presents a cloudy appearance, as if formed of milk and water imperfectly mixed. It is stated that if the eyeball is repeatedly rubbed with the finger through the medium of the eyelid, the clouds of opacity change their outline and position; and sometimes they do so merely on quick motion of the eye from side to side. The capsule is distended in cases of Morgagnian cataract, and pressing against the iris obliterates the posterior chamber and impedes the motions of the pupil. When the disease is purely Morgagnian vision is sometimes but slightly impaired, small objects escaping the observation of the patient, especially after the eye has been rubbed or moved, but after the lens dissolves, the sight is limited to the perception of light and shade." Mr. Lawrence says:—"Opacity of the fluid situated between the lens and its capsule has been called *cataracta Morgagniana;* but I doubt its separate existence. How can we determine that the fluid is opaque and the lens transparent? Can we suppose that this fluid is opaque and the lens remains transparent? I think, therefore, that in a practical consideration of the subject this kind of cataract might be safely omitted." Beer speaks of such a cataract occurring suddenly in consequence of exposure of the eye to acid vapours, and adds observations which render it doubtful whether he understood the nature of the disease at all. In the cataract to which I allude, I do not think that it is the fluid which is opaque, but the lens behind it, which is, I think, a common soft cataract. Mr. Mackenzie adds, that a "pure Morgagnian cataract is not to be touched in the way of operation." The cataract I have been alluding to I frequently operate on with success.

Notwithstanding the varieties of lenticular cataract, both of advanced and early life, above enumerated, many other forms of disorganization of this body might be described. I have seen the lens of a beautiful pale opaque green after general inflammation of the eye, and other curious appearances of it are occasionally met with; but the greatest amount of disorganization is found in congenital cataracts, and where the eye has been destroyed by the inflammation commonly called iritis, but which should be called ophthalmia. When this happens the pupil is generally adherent to a white, thickened, hard, opaque capsule, within which is a shrunk, friable, white fragment, bearing no resemblance in structure to the original lens, and in congenital cataract, as shall be noticed presently, similar or equally great disorganization is observed. These shreds of lens are, I believe, what are called siliquose cataracts. That the lens sometimes, but very rarely, has earthy matter deposited in its structure, most probably phosphate of lime, is an admitted fact, and one of interest in a physiological point of view, when it is recollected that the nutrition of this part has been attributed to a secreting process rather than to the usual growth by vascular ramification. Mr. Wardrop records an example of it, and I have myself seen streaks of white earthy material among the fibres of the lens in horses' eyes destroyed by inflammation. Mr. Wardrop describes it as "ossification of the lens," and states that "on dividing the crystalline lens its central portion was found converted into hard bone. The external laminæ of the lens were soft, but those nearer the centre became more consolidated, the central portion itself being of a deep brown colour, perfectly osseous, and exhibiting a laminated structure." And again, in his description of a plate of it:—"The ossification is seen commencing in the centre of the lens, and extending towards its circumference in the form of concentric bony laminæ. The central portion was a dark brown coloured and hard bone; the exterior laminæ were of a paler colour, and more friable." This example, thus authenticated, is of great value, because although ossifications of the capsule of the lens have been met with occasionally, conversion of the body of the lens into bone, or an earthy solid resembling it, is of extreme rarity. In the Medical Press of December 11, 1844 (vol. xii., p. 372), a very rare form of disorganization of the lens was noticed by me, having first been described at a meeting of the Surgical Society. About a week after breaking up a cataract in a boy's eye, which had been injured by a blow some years before, a quantity of small brilliant scales of metallic or micaceous lustre were found mixed up with the pulp of softened lens. They resembled fragments of gold leaf, or the particles of mica which are seen in granite sand, and remained undissolved for about six weeks, when they ultimately disappeared. There could be no mistake about the matter, as they were distinctly visible with the naked eye, and presented a very beautiful appearance when viewed with a powerful lens. On another occasion, after breaking up a cataract, the fragments which fell into the anterior chamber presented the appearance of the stearine of oil; and upon examination with a lens of short focus were found to be mixed up with needle-shaped crystals or spiculæ, about a line in length, which were after some weeks also absorbed. That these were not fragments of fibres of the lens I am convinced, because their crystalline character was distinct, and because they were not dissolved and absorbed for some weeks. I see no difficulty in admitting the possibility of

crystals of some of the phosphates forming in such a situation. The lens has been found sometimes, although rarely, in congenital cataract converted into a white milky fluid. Mr. Saunders records two, in which opaque capsules were found filled with such material. In fact, there seems to be no end to the variety in form, consistence, and colour, observed in cataracts of long standing, especially when congenital, or caused by inflammation or injury, but it would be tedious and superfluous to enumerate all these under different names. In alluding to the causes of cataract and the possibility of its spontaneous cure, it will be necessary to call attention to cataract from wounds or other injuries of the eye. Here it is only necessary to say, that such cataracts are of a bluish-white appearance, and irregular flocculent composition; sometimes, when the wound in the capsule is very small, presenting the stellate form; sometimes, when the rent is larger, projecting in the shape of a white fleecy mass through the pupil into the anterior chamber; and sometimes, when the whole face of the capsule is torn open, swelling out so as to fill up the whole anterior chamber up to the very back of the cornea.

(To be continued.)

PROCEEDINGS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Mr. Hodgson, President.

ON SOME SECONDARY PHYSIOLOGICAL EFFECTS PRODUCED BY ATMOSPHERIC ELECTRICITY. By Prof. Schonbein.

After referring to the more obvious effects of electricity upon the organs of sensation, and more especially those of smell and taste, and stating his belief that the peculiar odour observed when an electrical discharge takes place, or in the neighbourhood of points from which electricity is passing, is not due to the electricity itself, but caused by the presence of a peculiar matter which he has named ozone, the author proceeded to lay before us the opinions held respecting it—viz., that either pure or atmospheric oxygen, when exposed to the action of electricity, is transformed into this odoriferous body, which he was at first inclined to consider a peculiar peroxide of hydrogen, but which other eminent chemists believe to be merely an allotropic modification of oxygen. With reference to its exact composition he declines, however, to give a decided opinion. This body, whatever its actual nature may be, is a most powerful oxidizing agent; at ordinary temperatures, oxidizing silver, forming iodic acid from iodine, nitric acid from nitrogen; converting the acids ending in *ous* into those which end in *ic*, the salts which terminate in *ite* into those which ends in *ate*; metallic sulphurets into sulphates. It decomposes the gaseous components of hydrogen, with sulphur, selenium, phosphorus, iodine, arsenic, and antimony, and exerts many other energetic chemical actions, both on organic and inorganic substances. It has a strong electro-motive power, similar to that of chlorine, bromine, and iodine; and lastly, it has certain physiological effects upon the animal system, similar to those of chlorine and bromine, acting powerfully as a poison, even in minute doses. Ozone is being constantly generated in the atmosphere by the electrical action going on. When in excess it has a sensible effect upon the mucous membranes of those exposed to its influence, and its presence is indicated by starch containing the iodide of potassium being turned blue. The author has availed himself of this fact in the construction of his ozonometer, which consists of a box containing test-paper thus prepared, and a chromatic scale. He believes that certain catarrhal affections are produced by the presence of ozone in the atmosphere, and he has availed himself of the assistance of medical friends in ascertaining the coëxistence of unusual prevalence of catarrh with what he terms his *blue days*, and he suggests that more extended observations are desirable for this purpose. The author then referred to the existence of poisonous miasmata in the atmosphere, which are generated by certain "purely chemical, or physical, or physiologically chemical actions," which take place within the earth, or on its surface, in stagnant or running waters, or in the atmosphere itself. Of these poisonous gases or vapours, there are two sorts which are antagonistic to and destroy each other. Of the first class, sulphuretted, and perhaps phosphuretted, hydrogen, alone, are produced by natural causes, and these in such minute quantities that they do not, except in a few localities, exert any general influence upon animal life. Of the second class, there is one,—namely ozone, which exists in appreciable quantities in the atmosphere. But the abundant source of gaseous matters is that which the decomposition of vegetable and animal substances affords. Some of these are well known, such as carbonic acid and ammonia; others are of unknown chemical nature, and though the absolute quantity of such deleterious matters may be small in comparison to the immense volume of the atmosphere, their accumulation would render the air unfit for the support of animal life, unless some agent were at work to neutralize or decompose them. The author states, that the purification of the atmosphere which we attempt to effect on a small scale by chlorine fumigations, is accomplished in the great processes of nature by the agency of ozone, a task for which it is peculiarly fitted by its high oxidizing powers. He gives the details of some experiments upon air tainted by putrid flesh, which was purified by ozone disengaged by the action of moistened phosphorus. Ozone, which is formed in the atmosphere by the electrical discharges constantly going on, acts upon and decomposes the oxidizable miasmatic gaseous matters which contaminate it, and thus the atmosphere is preserved in a state fit for the support of animal life, and, at the same time, the ozone, which, if allowed to accumulate, would become deleterious, is in its turn neutralized or decomposed by the miasmata. During a thunder-storm large quantities of ozone are formed, and the author supposes that the unhealthy state of the atmosphere which exists in the hot season of the year may be caused by the accumulation of miasmata produced by animal decomposition; and that it is by the generation of ozone that thunder-storms purify the air. The author considers that there are probably certain states of the atmosphere in which the quantity of ozone does not bear a due proportion to the miasmata it has to act upon, and that under such circumstances it is that certain diseases—cholera, for instance—make their appearance. He is also of opinion, that in the winter there is more atmospheric ozone than in summer, and that the higher strata of the atmosphere contain more than the lower; and as the generation of some diseases, such as the yellow fever, appears to be connected with certain seasons and geographical positions, he thinks that by an extended series of observations it might be ascertained whether these diseases bear any relation to the ozoniferous state of that portion of the atmosphere where they happen to occur. The paper concludes with a reference to experiments which prove that ozone produced by the action of electricity or by the agency of phosphorus is identical.

ON A NEW METHOD OF TREATING CERTAIN CASES OF EPIPHORA. By William Bowman, F.R.S.

This paper describes a new mode of treatment of those cases of epiphora which depend on a displacement of the puncta lachrymalia out of the course of the tears, or on an obstruction of the canaliculi between the punctum and caruncle, the inner extremity of the canals, together with the lachrymal sac and nasal duct, remaining healthy. The author describes the exact nature of these cases, and relates examples. The treatment which he has devised consists in slitting up the canal from the punctum on the conjunctival aspect, so as to carry backwards the orifice at which the tears are received on to the mucous membrane near the caruncle; and he finds that the tears are in fact taken up by the remaining portion of the canal, while the end towards the punctum is converted into a groove. For the cases of obstruction from injury or other cause, he suggests a modification of this operation, by which the

canal between the obstruction and the sac may be slit up for some way, so as to receive the tears at a new opening. The cases to which these new operations are applicable, have been for the most part abandoned by surgeons as incurable.

DESCRIPTION OF AN OPERATION FOR THE RADICAL CURE OF OBSTINATE STRICTURE OF THE URETHRA. By Dr. Nevermaun of Mecklenburgh.

(Communicated by B. Phillips, F.R.S.)

The author states that after having tried all methods of treating obstinate stricture, the operation with a trocar catheter appears to him the most rational. The patient is placed as for lithotomy, and the catheter introduced as far as the seat of obstruction. The operator introduces one or two fingers into the rectum as a guide to the instrument; he then grasps the handle of the instrument, whose point is exposed, with the right hand, and pushes it steadily and forcibly forwards in the axis of the pelvis towards the bladder. When the resistance is found to cease, the trocar is drawn out and the catheter is left in the canal. In four or six days it is replaced by an ordinary elastic catheter. The paper is accompanied by drawings of the instruments and a description of them.

CASE OF OBTURATOR OR THYROIDAL HERNIA SUCCESSFULLY RELIEVED BY OPERATION. By Henry Obre, formerly Assistant-surgeon to the St. Marylebone Infirmary.

(Communicated by Professor Erichsen.)

After commenting on the extreme rarity of this form of hernia, and stating that he had been unable to find any record of its having been detected and relieved by operation during life, the author relates a case in which he operated successfully. The patient, a female aged 55, the mother of a large family, was seized with symptoms which led her medical attendant (Mr. Gardener) to believe that she was suffering from rupture. She denied that this was the case, and a careful examination convinced Mr. Gardener that there was no hernia in the usual situations of that disorder. A little below the femoral region on the right side, however, he detected a degree of hardness resembling a small gland, and deeply seated; with some general fulness about the part. The author saw this patient on the fourth day after the symptoms had begun; at this time, she was suffering extreme abdominal pain in the umbilical region; during the previous twelve hours, her vomiting had been stercoraceous and incessant; the countenance pale and contracted; voice faltering; pulse weak, small, and intermitting—in short, all the symptoms of pending dissolution from strangulated intestine were present. On careful examination, nothing could be detected but a slight degree of fulness in Scarpa's triangle on the right side; that on the opposite side being well marked; on using firm pressure with the ends of the fingers over the neighbourhood of the femoral artery, and a little below the saphenous opening, a distinct hardness was to be felt, slight in extent, but giving the impression as if the sheath of the vessels was being pressed on. The state of the patient was such as to induce the author to propose to make an incision into the upper part of the thigh, down to the hard structure, in the hope that he might find confined intestine low in the femoral canal. He made a straight incision into Scarpa's triangle, as in the operation for tying the common femoral artery; beginning about three inches below Poupart's ligament. When the cribriform fascia was opened, and the saphenous opening exposed, no hernial sac was found, but the hardened structure could be felt lying deep to the inside of this opening. The dissection was with some difficulty continued downwards; the fascia lata was divided, and the pectinæus muscle exposed. The fibres of this muscle were divided transversely for about an inch and a half or two inches, and a hernial sac was exposed, which rose up into the wound to the size of a pigeon's egg. The finger being passed along the sac, entered the obturator opening. The sac was opened, and the intestine was found to be a portion of the small gut, blue and congested. The opening through which it passed did not tightly enclose its neck, but it was considered prudent slightly to divide the edge. In doing this the saphena vein was wounded, and it was necessary to apply a ligature to its upper part. This was the only ligature required. After the operation, no medicine was given; in the course of the day the bowels acted three times, and in the course of a few days the patient had quite recovered.

SOME OBSERVATIONS ON THE PATHOLOGY OF THOSE AFFECTIONS OF THE EAR WHICH PRODUCE DISEASE IN THE BRAIN. By Joseph Toynbee, F.R.S.

In this communication the author has a two-fold object: the first is to point out the nature of the several affections of the ear which produce disease in the brain; the second to show that each of the cavities of the ear has its particular division of the encephalon, to which it communicates disease. Thus, that—

1. Affections of the external meatus and mastoid cells produce disease in the lateral sinus and cerebellum.

2. Affections of the tympanic cavity produce disease in the cerebrum.

3. Affections of the vestibule and cochlea produce disease in the medulla oblongata.

1. In speaking of the external meatus, its intimate relations with the lateral sinus and cerebellum are pointed out; the affection most frequently producing disease in these parts is shown to be catarrhal inflammation of its dermoid layer, one of the numerous diseases which have hitherto been classed together under the term otorrhœa. This affection of the external meatus is fully described; and it is shown that it is found to endure during many years, without the presence of pain, or any other symptom calculated to apprize the surgeon of the presence of a formidable disease, while the bone may be becoming slowly carious, and portions of the dura mater and cerebellum disorganized.

In the second division of the paper, the tympanic cavity is described to be the part of the ear from which disease is most frequently propagated to the brain. This circumstance is accounted for, firstly, by the great liability of the mucous membrane of the tympanum to undergo pathological changes; and, secondly, by the existence of very intimate relations between this membrane and the dura mater. The affection of the tympanum which most frequently produces disease in the cerebrum is chronic catarrhal inflammation of the mucous membrane, an affection thus far only known as an otorrhœa. The four changes in the dura mater and cerebrum produced by the affections of the tympanum are—

1. Inflammation of the dura mater, and its separation from the surface of the petrous bone by serum.

2. Ulceration of the dura mater, and its complete detachment from the petrous bone.

3. An abscess in the substance of the cerebrum.

4. Undefined suppuration of the substance of the cerebrum.

From a careful examination of cases, it appears that chronic catarrhal inflammation of the mucous membrane of the tympanum may exist as many as twenty or more years, without the production of any disease beyond it, or at least without the existence of symptoms by means of which the presence of such disease can be diagnosed; nevertheless, in the great majority of cases, vital structures become sensibly affected in a much shorter period.

The third section of the paper is devoted to the consideration of the labyrinth, and it is shown that purulent matter in the vestibule or cochlea, sometimes causes disease of the auditory nerve, which is transmitted to the medulla oblongata, producing suppurative inflammation of the meninges, and death, without the presence of any caries of the bone.

In the course of this paper, the author shows the necessity of abolishing the use of the term otorrhœa, and of using in its place the names of the several diseases, eight in number, of which a discharge from the ear is one of the symptoms. In conclusion, the facts which he is desirous

of impressing upon the minds of medical men are, that the bone, dura mater, and substance of the brain may be slowly undergoing disorganization, without the presence of any other symptoms calculated to reveal to the medical man the existence of formidable disease, than the presence of a discharge from the external auditory meatus; and that consequently no person suffering from catarrhal inflammation of the dermoid layer of the meatus, the membrana tympani, or of the mucous membrane of the tympanum, can be assured that disease is not being prolonged to the temporal bone, the brain, and its membranes; and that any ordinary exciting cause, as an attack of fever or influenza, a blow on the head, &c., may not induce the appearance of acute symptoms, which, as a general rule, are speedily fatal. Appended to the paper are tables, giving the particulars of sixty-five cases of disease extending from the ear to the brain, in which tables the duration of the chronic and acute symptoms, and the post-mortem appearances, are concisely detailed.

A CASE OF OBSTRUCTION OF THE COLON RELIEVED BY AN OPERATION PERFORMED AT THE GROIN. By James Luke, Senior Surgeon to the London and St. Luke's Hospitals.

(Communicated by James Moncrieff Arnott.)

The subject of this report was a man aged 60, who, on December 16, 1850, first complained to the author of feeling generally unwell. He had no pain, but his countenance was depressed, his eyes sallow, and his tongue coated. The bowels were confined, and lately medicines had acted with difficulty on them. An aperient was ordered, and on the following day he passed a small lumpy motion, but without relief to the symptoms; castor oil was ordered, but after a time was rejected by vomiting. On the 18th there was no relief from the bowels and he vomited everything he took. From this time he progressively got worse in spite of all the means resorted to for his relief. He complained of pain chiefly about the region of the cæcum. The transverse arch of the colon could be felt distended and tympanitic. A careful observation of the case had led the author to believe that there was obstruction in the bowel about the sigmoid flexure of the colon, and it was resolved as a last resource to operate upon the patient. The operation was performed on the 23rd. Not thinking it prudent to assume that the conclusion respecting the seat of the obstruction was certainly correct, the author determined to adopt that operation which would give him some opportunity of extending his search, provided he did not find the obstruction at the point where it was supposed to be. He therefore opened the abdominal parietes near the groin, by an incision four inches in length, a little to the outside of the course of the epigastric artery, the lower extremity of which incision terminated a little above Poupart's ligament. The peritoneum was opened to the extent of about two inches. On passing the finger down the surface of the intestine, which now protruded, a diseased mass could be felt, which appeared to encircle the intestines. The bowel was then opened above this part; a large quantity of feculent matter came away and the patient expressed himself as relieved. On now passing the finger into the bowel it was found to be impervious about two inches below the aperture. After the operation the recovery of the patient was rapid. On the second day, fæces passed per anum, and continued to do so for more than a month, when their passage through the natural opening ceased; it was again partially restored, but from this time the greater part of the fæces passed by the wound. This is closed by a well-fitted pad, and he has been enabled since to pursue his ordinary occupation almost without interruption. The author then proceeds to remark on the danger of protracted delay in attempting to relieve such cases, a delay which is, however, to a great extent rendered necessary by the difficulties of diagnosis. The distention of the colon, and the evidence afforded by the proper introduction of the long tube, are pointed out as the two means of diagnosis on which reliance may be generally placed for the purpose of determining the seat of obstruction, when it is situated at the lower part of the colon. The advantages of the operations of Amussat and Littre are then compared, and the author, while admitting the advantage gained by operating in the loins, as proposed by the former—of not opening the peritoneal cavity—yet thinks that the operation in the groin offers certain advantages which render it in many cases preferable. By the operation in the loins nothing more could be done than opening the intestine; but this might in some cases be improper—as where obstructions were produced by fibrous bands overlying the intestine, or by strangulations, the result of causes acting exteriorly to its tunics. In these cases, the proper treatment is to divide the bands, or relieve the cause of strangulation. In the event, too, of an error of diagnosis, the opening in the loins does not provide any facilities for correcting the error. The danger of total failure of affording relief consequent upon this state of things, must therefore be attributable as a demerit to the operation in the loins. There are, besides the minor evils in this operation, that the opening cannot be conveniently attended to by the patient himself, and that there exists frequently a great disposition to contraction, arising from the great depth of the wound, which requires renewed surgical interference. In all these particulars, with the exception of the necessary attendant of peritoneal section, the operation of opening the abdominal parietes at the groin, in all cases of obstruction, or suspected obstruction, in the lower part of the colon, appears to the author to be the operation which should be preferred. It affords facilities for modifying the treatment, either by opening the intestine, when incapable of relief by other means, or by dividing or removing any existing cause of strangulation. It enables the surgeon to extend his search within a limited range, in the event of the diagnosis proving incorrect; it allows him to open the bowel as close as possible to the seat of obstruction; and it secures to the patient the facilities for attending to his own comfort which appear almost a necessary condition to make life endurable under such circumstances.

ABSTRACT OF A PAPER ON THE VARIATIONS OF THE SULPHATES AND PHOSPHATES EXCRETED IN ACUTE CHOREA, DELIRIUM TREMENS, AND INFLAMMATION OF THE BRAIN. By H. Bence Jones, M.D.

Having determined the variations of the sulphates in the states of health when different diets, amount of exercise, and medicines were taken, the variations of the sulphates in disease were examined. At the same time the total amount of alkaline and earthy phosphates was determined, partly in order to see whether the amount of sulphates and of phosphates bore any relation to one another, and partly to test the conclusions which were drawn in the author's previous paper on the Variations of the Phosphates in Disease. The cases were thus classified.

1st. Acute and chronic diseases, in which the muscular structures were chiefly affected, as chorea.

2nd. Functional diseases of the brain, as delirium tremens.

3rd. Acute inflammatory diseases of the nervous structures, as inflammation of the brain.

4th. Chronic diseases of the nervous structures.

5th. Acute diseases, in which neither the nervous nor the muscular structures were chiefly affected.

6th. Chronic diseases, in which neither the muscular nor the nervous structures were chiefly affected.

The three last classes gave only negative results.

In illustration of the first class, three cases of most intense chorea are detailed; the urine was examined frequently from the third to the eleventh day. The phosphates were found to be diminished. The sulphates were present in very great excess. The urine was found to be so loaded with urea, that nitrate of urea crystallized out before the urine was concentrated. The specific gravity of the urine was as high as 1036 in one case, 1035 in another, and in the third, 1031.

In illustration of the second class, three cases of delirium tremens are given. The urine was examined from the fifth to the fourteenth day of the disease. The phosphates were not found to be so remarkably diminished

as in the cases reported in the previous paper. The sulphates were found to be exceedingly increased. The amount of urea was so great, that nitric acid caused an instantaneous crystallization. The specific gravity also was in one case, 1041 ; in another, 1037 ; and in the third, 1027. In other words, there was the most remarkable correspondence between the state of the urine in acute chorea and in delirium tremens.

In illustration of the third class, four cases of acute inflammation of the brain are given. The urine was examined from the fourth to the twenty-sixth day. Though the inflammation in these cases was not so intense as in those which were recorded in the author's previous paper referred to, yet they confirm the statement that in inflammation of the brain the phosphates in the urine are increased ; they also lead to the conclusion that the sulphates are at the same time increased in the same degree.

In conclusion, the author states, the phenomenon common to acute chorea and to intense delirium tremens is increased and unceasing muscular action. The muscles are highly complex organic compounds, in which sulphur exists in an unoxidized state, and the muscular action is accompanied, if not caused, by an action of oxygen, which, among other results, gives rise to the formation of sulphuric acid and urea, the amount of oxidation being proportioned to the intensity of the muscular action. The result produced is an increase of the sulphates and of the urea in the urine, just as in health they would be increased if continued strong exercise were taken. The increased amount of urea does not constitute a disease resembling diabetes, but it is only an evidence of the changes which are taking place within. The increase of sulphates and phosphates in inflammation of the brain is also an evidence of increased oxidation of the nervous structures. These simultaneous variations depend on the fact that the amount of sulphur in the brain is nearly the same as the amount of phosphorus. Thus at one time we have evidence of increased oxidation of the elements of the nervous structures, and at another time increased oxidation of the elements of the muscular structures ; and we may thus arrive at the conclusion, that at one time the function of the nerves and at another that of the muscles, is inordinately increased.

ON TEETHING.

(From a Treatise on the Teeth by Mr. A. Canton.)

(Continued from p. 26.)

A BOY of my own, fifteen months old, during dentition, was discovered at one o'clock one morning in a state of stupor, and quite insensible to external impressions, he having previously manifested an extraordinary tendency to sleep. The limbs were all powerless, and apparently paralytic. The irritation of the brain which caused these symptoms, was excited by the process of dentition, which was going on with reference to the canine teeth, the apices of which were just perceptible above the gum. The poor little fellow was placed in a warm bath, leeches were applied to the temples, a blister to the nape of the neck, and the gums were freely lanced. He nevertheless remained in a state of stupor for a day and a night. Calomel, and the other remedies requisite in such cases were employed, and at the end of that time he became sensible, and shortly afterwards recovered the use of his limbs. He remained, however, more or less ill and suffering until the teeth, which had barely pierced the gum at the commencement of the attack, were fairly through. His health was not quite reëstablished till after the lapse of a month. Several cases of palsy affecting one arm, caused by dentition, have fallen under my notice. The operation of lancing the gums, and the employment of appropriate remedies, have generally sufficed to effect a cure in a shorter or longer period of time.

These are instances of great severity of disease caused in these poor little sufferers by neglecting the indications of approaching dentition, or by the sudden and very great irritation which it sometimes sets up in the system. The next case I shall mention is one of a singularly anomalous nature, but clearly dependent on teething for its cause. My friend Mr Whitmore, a surgeon practising in Oxford-street, has furnished me with the particulars of an interesting case under his care, exhibiting one of the anomalous results attending dentition. A female infant, seven months old—at birth a fine and perfectly healthy baby—became fretful and restless, evidently suffering from the irritation consequent on cutting her first tooth. There were heat of mouth, some swelling of the gums, and slight derangement of the bowels. This state continued a few days, when one morning, whilst dressing her, her mamma felt something beneath the skin of the abdomen, about an inch and a half obliquely to the left of the navel, which on each inspiration was forcibly propelled to the surface, as though it would protrude through the skin. On careful examination, it was found to be blunt-pointed, of a hard cartilaginous feel, and in size and shape resembling a very small *tin-tack*. Handling it, or even forcibly pressing it, caused no pain. The child was seen by Dr. H. Davies and Mr. Beale, neither of whom expressed any decided opinion as to the nature or character of the small tumour. On the second morning after this, it entirely disappeared, and simultaneously as it were appeared a tooth, the front incisor of the left side of the lower jaw. The little swelling reappeared a few days afterwards, again to disappear on the cutting of another tooth. A tooth was next cut in the upper jaw ; no swelling was observed on that nor on a subsequent occasion. It was in all probability a swollen sebaceous gland, its enlargement being owing to the irritation of the bowels, caused by teething.

Cases out of number might be brought forward to illustrate the serious consequences which are the result of teething. Those already given are, however, sufficient to warn affectionate parents of the dangers that await their offspring during this, the most hazardous period of infancy.

It is, however, advisable to state that, at a meeting of the Fellows of the Medical Society of London, in December last year, it was the unanimous opinion of the medical men present, that that very formidable disease, *laryngismus stridulus*—the crowing inspiration of infants, was, in the majority of instances, dependent on dentition, and to be prevented or cured by such measures as will remove its committant irritation.

Drs. Evanson and Maunsell, in their work on the Diseases of Children, support the views previously advanced, as to the dangers attending teething, in the following words:—"The more suddenly the teeth are developed, and the greater the number coming out together, the more will be the local irritation, particularly should any obstacle be presented, as a disproportion between the rate of development of the teeth and the jaws. The earlier the age at which dentition commences, the severer is likely to be the constitutional disturbance, from the greater susceptibility of the system : for the natural susceptibility is heightened by the rapid evolution which the brain is undergoing at this early period, in addition to which there is local determination of the blood, caused by the process going on, so that the nervous system is in the highest state of irritability ; hence is symptomatic disturbance of all parts, but more particularly of the brain, so liable to be induced at the time of teething. The proneness to this will be increased by anything that tends to deteriorate the general health, as the injurious effects of improper food, bad air, &c. Delicate children suffer more constantly than the robust, their dentition being tedious ; and in them bowel complaints, with wasting, frequently attend. Any complaint, in short, to which a predisposition may have existed, is likely now to be developed ; and any disease contracted at this time (as measles, &c.) is attended with additional danger."

This is not the place to dwell on the treatment of such cases ; that task belongs to the medical practitioner, who should be at once summoned when symptoms indicative of disordered health arise during teething. It is impossible, however, to refrain from making some remarks respecting the necessity of lancing the gums during denti-

tion—a slight surgical operation productive of the utmost relief to the little sufferer, but to which many parents, most unwisely and unaccountably, offer the most determined opposition. No one can feel surprised at the various disorders and their severity which are set up in the system during teething, when it is recollected that the process itself is attended with considerable local suffering and inflammation, and that the little patient is at a period of life, when the nerves are most prone to receive impressions, and most subject to external and internal causes of excitement. The tooth which has to make its way into the mouth from within the follicle in the socket, in which it had hitherto been confined, has, by means of pressure from behind, to cause absorption of all the parts which impede its progress. This is necessarily a work of time; the gum and the mucous membrane covering it, do not readily yield to the powers of the absorbents; inflammation is set up, the parts are put upon the stretch, the small nerves which supply them with sensation partake in the inflammation, and become exquisitely sensitive, but still they do not yield. And consequently one or other of the disorders and diseases, to which we have alluded, is induced; the child becomes much worse in its health; all the previous symptoms are aggravated, and unless some decided step be taken, its life will be lost. What step so ready, so necessary, so clearly pointed out by nature, as that of lancing the gums?

Medicine and surgery have been defined as the arts by which nature is to be aided in her operations. What under these circumstances is the process nature adopts? By a slow and unequal action, the edge of the tooth makes its painful way through a swollen and inflamed gum, the absorption of every atom of which being the cause of severe suffering, and perhaps of irremediable mischief to the little victim of mistaken and misguided affection. And why do parents object to this simple operation? Because an old woman's tale supports the ridiculous theory that the *cicatrix*, or scar resulting from the lancing, will be more difficult for the tooth to pierce through, than the sound or at least the previously unwounded gum would be. This is an error that few educated persons in the present day would venture to support. The newly-united part, where the incision has been made, is absorbed much more readily under the pressure of the tooth, as it advances externally, than would be the original sound gum, and tough mucous membrane covering it, because it being of more recent formation, and the result of effused lymph, has a less degree of vitality or life to resist the pressure of the tooth.

In sea-scurvy, a disease which formerly devastated our fleets, destroying the seamen, so that in Anson's time, our ships of war were frequently less than half manned: in that fearful disease it was found that when the sailors had previously suffered from wounds, or ulcers, or broken bones, of no matter how ancient a date, the cicatrices gave way, and the solder of the broken bone yielded, while the other sound and uninjured flesh remained intact and unimpaired. In like manner then, as in sea-scurvy, the parts previously wounded, or ulcered, yield sooner than those which are sound, so the cicatrix, left after the gum has been lanced, will also yield more readily than would the gum, if it had never been incised. But even supposing it were true that the hardened scar would be absorbed with greater difficulty, and the process of teething become thereby more protracted, is that to be alleged as a reason why the operation of lancing the gums is never to be practised, and the unfortunate little sufferers to be left, to bear the agonies of pain and inflammation in the mouth, and the more general disorders caused in the frame by the irritation thus set up? Is the life of the infant to be endangered and sacrificed by the non-performance of an operation, slight in itself, unattended with danger, and causing but little suffering; and which, when practised in time, invariably affords relief? The result so much feared by mothers and nurses—the greater impediment to the passage of the tooth—can be averted or remedied by the repetition of the operation. The hardened gum—always supposing it to increase the difficulty, which it does not—can be divided and separated by the gum-lancet, from time to time, not only without risk of danger, but with manifest benefit and relief to the infant. It is an operation which is serviceable, first by removing the tension of the gum, and of the small nerveletts in it which are strained and stretched by the protruding, compressing tooth; and secondly, it affords relief by the slight loss of blood which follows, and which serves to lessen the attendant inflammation.

In some cases, where the brain is in a state of great irritation, convulsive fits rapidly succeeding each other, each one being worse than its predecessor; and in many others also, where the general disordered condition of the internal organs runs high, it becomes necessary to have recourse to lancing the gums daily, and even more frequently still, in addition to other remedial measures, in order to keep down the local inflammation and irritation.

In Dr. Marshall Hall's Observations on Medicine, page 30, there is a chapter of so much value and truth on this very subject, that, were it not that space forbids, as it would add so much to the strength of our argument, we would willingly transcribe the whole. It is entitled, "On the motive for the scarification of the gums during dentition." We must content ourselves with making some extracts from it. He observes, p. 30:—"There is no practical fact of the truth and value of which I am more satisfied, than that of the effect and efficacy of scarification of the gums in infants, and not in infants only, but in children. But the prevailing, I may say the universal, idea on this subject is, that we should lance the gums only when the teeth are ready to pierce through them, and only at the most prominent parts of the gums, and as the occasion to which I have referred may require; and no idea of this important measure can be more inadequate to its real value. The process of teething is one of augmented arterial action and of vascular action generally; but it is also one of augmented nervous action; for formation, like nutrition, secretion, &c., generally, is always one of nervo-vascular action; and of this the case in question is, from its peculiar rapidity, one of the most energetic. Like other physiological processes, it is apt to become, from that very character of energy, pathological, or of morbid activity. It is obviously, then, attended with extreme suffering to the little patient; the brain is irritable, and the child is restless and cross; the gums are tumid and heated; there is fever, an affection of the general vascular system, and there are, too frequently, convulsions of various degrees and kinds, manifested in the muscles which move the eyeball, the thumb and finger, the toes; the larynx, the parietes of the respiratory cavities; and the limbs and frame in general, affections of the excito-motor part of the nervous system, and of the secretion of the liver, kidneys, and intestines, affections of the ganglionic division of that system."

Dr. M. Hall next examines the causes which lead to such extensive and varied irritations in the systems of children, which he considers to be seated, not in the gums alone, but in the entire dental system; and then strongly recommends the scarification of the base of the gums, as well as of the apex, and he remarks:—"Better scarify the gums *unnecessarily* one hundred times, than allow the accession of one fit of convulsions from the neglect of this operation, which is equally important in its results, and trifling in its character. And it is not merely the prominent and tense gums over the edges of the teeth which should be divided; the gums, or rather the bloodvessels, immediately over the very *nerves of the teeth* should be scarified and divided. Now, whilst there is fever or restlessness, or tendency to spasm, or convulsion, this *local bloodletting* should be repeated daily, and in urgent cases even twice a day. * * * A skilful person does it in a minute, and in a minute often prevents a most serious attack; an attack which may cripple the mind, or the limbs, or even take the life of the little patient, if frequently repeated. There is, in fact, no comparison between the means and the end: the one is trifling, and the other so momentous."

Nor is it, he asserts, only while the teeth are making their way through the gums that scarification or lancing should be practised. The most marked case in which he observed the instant good effect of scarification, was one in which *all the teeth had pierced the gums.* "And there is," he says, "a phrase among nurses—viz., 'the breeding of the teeth,' which may be taken as evidence that *before* the teeth actually reach the borders of the gums, they may prove the source of much irritation."

Can words of greater power be used, to urge and enforce on parents the absolute necessity for this operation under the circumstances we have indicated? The restoration of health, the preservation of life, and of the powers of the mind and body, may frequently be ensured by the careful and appropriate use of a small piece of steel on the inflamed gums of an infant; and on the other hand, all these may be and are frequently endangered by its neglect, owing mostly to the unwise, and unaccountable opposition of parents, or of an ignorant or prejudiced nurse. It seems strange that such a prejudice should still exist, but it does so unfortunately, and it is the duty of every one to do his utmost to eradicate it.

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, JULY 16, 1851.

RESULTS OF UNIVERSITY DABBLING IN MEDICAL EDUCATION.

The following, evidently written without reference to the late proceedings of the New Irish University, indeed in ignorance of them, is still so *apropos* that we copy it for the instruction of our readers. That the London University has already failed as an institution for the conferring of medical qualifications cannot, we believe, be denied; and that it has failed in consequence of its unfitness for such duty appears equally admitted. With the education, examination, and licensing of medical practitioners, such an institution had no more pretension to interfere than it had to interfere with the "calling" of barristers, or the ordaining of clergy. Its mission was and is to prepare candidates for entrance upon the study of medicine; and to that, if its managers have any prudence, they will restrict themselves:—

Contrasted with the endowments, the privileges, and the free constitutions of her elder sisters, the University of London exhibits a singular anomaly. The university of the metropolis—the university of civil and religious freedom—the university which is the latest, although still imperfect, expression of the progress of the human mind in the long struggle for the emancipation of philosophy, science, and art from religious domination—the university which is the practical embodiment of the principle of the nineteenth century, is without the faculty of self-government. It depends for its existence upon an annual grant from parliament, and the fluctuating views of the individual whom the alternations of party strife may for the time being raise to the unstable office of Secretary of State. The constitution of the university has no independent element of vitality; her graduates—those who are linked to her principles, and whose interests are involved in her future destinies by education, early associations, and even stronger ties—have no position within the charter, no voice in the government. The maintenance of those great principles upon which the metropolitan university is based, is confided to a small body, the immediate nominees of the Secretary of State. Every change of administration brings a change in the person holding this office, and most probably a change in the sentiments which animate the behaviour of government towards the dependent university. Will it be advanced, that in the senate there exists a guarantee for its vigorous and consistent government, and, above all, for the perpetuity of its leading principle? That last hope the senate themselves have dispelled. When they entered upon office they foresaw, what experience has now confirmed, that a body constituted as they were, was neither adapted for the full and public expression of the functions of the new university, nor to guide it in its future growth. As was shown on a former occasion, they applied themselves to the task of providing a constitution more suitable to the purpose. The original senate in 1840 did this. But they seem to have mistaken their position. They had acted as independent men, invested with general discretionary powers to promote to the best of their judgment the high objects of the university. They had yet to discover that they were the mere agents of a higher power. In 1850, the vacancies time had created in their number were filled up by the Secretary of State. Among the new members were found four individuals who had held prominent positions in the present or former administrations. Possibly this circumstance may help to explain the opposite views the senate of 1840 and the senate of 1851 have taken of their functions. They now avow themselves to be the mere exponents of the wishes of the Secretary of State. They now discover that "this question (of the constitution of the university) is not one which they can with propriety discuss." "They act under the superintendence of the Secretary of State." This, then, is the condition of the university! The graduates have no status whatever: the senate formally acknowledges that it has no independent authority. It merely executes certain routine duties under the superintendence of the Secretary of State. Besides the government, who are presumed to act for the general good, and who may be regarded as only indirectly interested in this question, there are three parties more or less deeply concerned—the senate, the graduates, and the public. We ask each one of these whether the present position of the University of London is satisfactory? whether it is conducive to its development, and to the effective spread of an enlightened system of education? and, lastly, whether it affords the guarantee which the public have a right to demand—that the fundamental principle of the university, the freedom from religious tests, shall be preserved. As a portion of the public we broadly answer this last question with a decided negative. *We have no security whatever.* We might show that no body constituted on the plan of the university can offer the necessary security. We could show, and we shall probably deem it our duty to show, that, EVEN NOW, the principle of religious freedom which the University of London was founded to protect, is in the most imminent jeopardy. We will not presume to answer the questions proposed on behalf of the two other parties—the senate and the graduates. The graduates, indeed, have already answered for themselves. For three years have they, with remarkable unanimity and laudable disinterestedness of purpose, repeated their practical conviction that they find under the present system no safeguard for the permanent welfare of the university, no ground for confidence that the integrity of its fundamental principles will be upheld. And assuredly this distrust will not be removed by the declaration of the senate, "that they act under the superintendence of the Secretary of State." But if we cannot answer this question for the senate, it is at least competent for us to ask them another. We will ask them if an office of servile dependence upon a minister—an office in the execution of which they are required to carry out to the letter the restricted duties of a mere examining board, without heed for, or liberty to promote, the final object of the institution at the head of which they are ostensibly placed—is an office befitting them to hold? Can it be that men whose names are illustrious in the ranks of the advocates of freedom, are prepared to repudiate the principle of representation? Have they who have so patiently traced the history and dwelt upon the advantages of constitutional institutions, so little faith that they dare not recommend the extension of the system in an instance where they possess the power to give effect to their opinions? Some of them are members of the older universities. Will they be guilty of the inconsistency, of the injustice, of denying to the graduates of the University of London the privileges they themselves enjoy? Have they forgotten, that on the foundation of the University of London, it was made a deliberate promise and condition that the new university should have powers coextensive with those of Oxford and Cambridge; that the new graduates should not be in an inferior position to the old; that henceforth it should not be said that the members of the State-religion monopolized all academical honours, functions, and privileges? Will the senate be the instruments in falsifying that pledge which consecrated the new university whose interests they were appointed to guard? —*Lancet.*

PHARMACY BILL.

Looking upon this as a measure of the first importance, we are anxious to make our readers acquainted with its objects, which we cannot do better than by reporting the late statements in the House of Commons respecting it. The bill has been amended in committee, but will not be pressed until next session:—

HOUSE OF COMMONS.—WEDNESDAY, JULY 2.

Mr. Jacob Bell rose to move the second reading of the Pharmacy Bill, the object of which was to improve the qualifications of the pharmaceutical chemists; and the principle of which was, that all those who compounded the prescriptions of medical men should be educated, and should pass an examination. If it were necessary for physicians to pass an examination before they were permitted to practise, it was of course of equal importance that the persons who furnished the remedies they prescribed should be able strictly to obey the directions of the physicians. The first incorporation of apothecaries took place in the year 1617, that body then holding the position which pharmaceutical chemists occupied at the present day. The number then incorporated was 114, that being the number of the physicians. In 1694, their growing importance was shown by their being exempted from serving on juries. In 1748, a new charter of incorporation was granted to them. In 1815 an act was passed, called the Apothecaries' Act, which contained some exemptions that in great part frustrated its object. One was in favour of the chemists and druggists, for they had increased so much, and had obtained so much importance, that it was impossible to bring the bill through the house without some compromise. A clause in that bill, therefore, exempted chemists and druggists from its operation. The examination of the Apothecaries' Company was a general one, and comprehended medical practice in all its branches. Up to the present time, the apothecaries, who had now become general practitioners, had been gradually receding from pharmacy, and had become more identified with medicine and surgery, while the chemists and druggists had taken the place which had been left vacant by the apothecaries. In 1834, a parliamentary committee was appointed to inquire into the laws which regulated the medical profession. Several bills, about nine, had been since introduced for the regulation of the profession, Four of these bills had proposed to include chemists and druggists in their provisions, the object being to provide for an education and examination of the dispensers of medicine which should make them as competent to perform their duties as were the prescribers of medicine. But the most determined opposition had been made to these bills by the chemists and druggists, because it was proposed to place them under the Apothecaries' Company for examination. It was not to be supposed that the chemists and druggists would consent to be placed under the jurisdiction of the Apothecaries' Company. They had no objection to the improvement of the education of the body, but they opposed the bills that referred them to the hall for their diplomas. The honourable member for Kinsale (Mr. Hawes) left out this clause from the bill he introduced, but then the chemists and druggists regarded it as an insult that they should not be recognized as being in existence. They then organized themselves into a body, and in 1843 obtained a royal charter of incorporation. That body had since that time been in active operation, and had effected considerable good. But the pharmaceutical chemists of this country were still far behind those of France and Germany in point of education; but if the present movement should extend the powers of the society, there was no reason to doubt that in the course of ten or twenty years the pharmaceutical chemists of England would be superior to those of any other country. At present, however, if an individual came before them for examination, and was declared by them to be incompetent, he had nothing to do but to commence business, ignorant though he might be: he might snap his fingers at the examiners, and their examination went for nothing. The object of the bill was not to give a medical character to the body, but to make it strictly pharmaceutical. The bill was not so stringent in its provisions as any of the medical or pharmacy bills hitherto introduced. It did not propose a penalty upon the person who sold an ounce of Epsom salts; it only imposed a penalty upon persons who should deceive the public by assuming a name that did not belong to them. After a certain time it prohibited unqualified persons from assuming names to which they were not entitled; but after a man had commenced business it would be unjust for the law to step in and prevent him from obtaining his daily bread. Any improvement in the qualifications of such a body must be gradual. What parliament could do was to prevent the evil from going any further, and as each individual went off the stage his place would be supplied by one who had received a suitable education. By this means, in about ten or twenty years, a great improvement would be visible. It was not the year 1851 they were legislating for, but 1860 or 1870, and by that time he (Mr. Bell) expected to see a great improvement manifest. The bill might not be perfect, and certain amendments might be introduced in committee. But it was by the union of that house with the parties concerned that the desired object might be effected. He was told there was no chance of passing this bill, because it was connected with the medical profession, and because the condition of that entire profession ought to be legislated for in one measure. But any bill comprehending the rights and position of that profession had always been opposed, and care had been taken to keep the present bill distinct and isolated. He hoped that it would pass without much difficulty, and he deprecated its postponement to another session, from which great mischief would arise. If the bill was to become the law of the land at all, the sooner it passed, and the sooner the educational improvement commenced which it was the design of this bill to secure, the better it would be for the public. It was said that a bill of this sort ought to emanate from the Home Office. Nothing would have induced him to bring forward a measure on this subject if her Majesty's ministers could have been persuaded to undertake it. But during the last six or eight years numerous memorials to the Secretary of State for the Home Department, and petitions to that house, had been presented from chemists and druggists in all parts of the kingdom, praying for such a bill. He had now introduced it, with the permission of the Secretary of State, but if it were objected that it ought not to be in private hands, he should be glad to hand it over to the Home Secretary. He believed that it would be a great benefit to the public and to the profession, and he therefore moved that the bill be read a second time.

Mr. Hume said that when the house had had before it for the last twenty years one bill after another legislating for the medical profession, he had not much faith in the success of any measure professing to regulate that profession. This and preceding governments had found difficulty enough in dealing with the three medical bodies already in existence—the College of Physicians, the College of Surgeons, and the Apothecaries' Company; and now it was proposed to add another incorporated body to the number. The chemists and druggists were exempted by their own request from the provisions of the Apothecaries' Act of 1815. The honourable gentleman said that the Apothecaries' Company had gone to another sphere, and that they had become medical practitioners; but in his opinion the duty proposed to be devolved upon this pharmaceutical body ought to be the duty of the Apothecaries' Company. He wished to know whether any inquiry had been made by the government of the three established bodies to know whether the duties proposed to be given to the new body could or ought to be performed by any of them. It appeared to him that the addition of a fourth parliamentary body of medical men, invested with a monopoly in its particular business, would only complicate the difficulties of the subject, and interfere with that general measure which it was so essential to have enacted for the regulation of the medical and surgical profession at large. The chemists and druggists were doubtless a very valuable set of men, but it was quite undesirable to remove them from the sphere to which they properly appertained, and in which their usefulness developed itself.

Mr. Bernal said the honourable member for Montrose seemed unaware of that progress of public opinion which imperatively demanded that the class of men practising the business of chemist and druggist should be greatly elevated in the scale of science and knowledge. At present he was afraid there were but too many persons employed as chemists' assistants who did not comprehend the difference between oxalic acid and Epsom salts, and to whom the refinements of iodine, of aconite, and other developments of recent science, were altogether unknown.

Mr. Henley considered that the bill in its present shape would not effect the object contemplated. There was an utter absence of accurate definition of the persons who were to be entitled to sell drugs, or of the drugs they were to be entitled to sell; and there was no provision against the sale

of patent medicines, or proprietary medicines of any kind, however deleterious their materials might notoriously be.

Sir G. Grey said he had already, in conversation, suggested to the honourable gentleman behind him, and he would now suggest to him publicly, that this being a measure upon a subject of great importance, and of which the details were necessarily complicated, it was advisable that it should in some shape be for a reasonable time under the consideration of the profession and of the public before it was discussed in that house. The best course he thought would be to read the bill a second time *pro formâ*, and then postpone the further progress of the measure until next session, so that the public might meantime have an opportunity of ascertaining what the remedy proposed by the honourable member for admitted evils really was.

Mr. Cardwell concurred in the expediency of the suggestion made by the right honourable baronet.

Mr. Ewart was quite as much an advocate for some comprehensive measure on this subject as the honourable member for Montrose, but he felt that, in default of a general measure, a special measure that was likely to do good should not be rejected. Undoubtedly, however, the provisions of the bill should be thoroughly investigated.

Mr. Bell was quite willing to adopt the suggestion which had been made, and to have the bill now read *pro formâ*, with the purpose of introducing before next session such valid amendments as had been and might be suggested.

The bill was then read a second time *pro formâ*, and ordered to be reprinted.

Friday, July 4.

Mr. Wakley said the Pharmacy Bill had been read a second time on the understanding that it would go into committee on Wednesday *pro formâ*, in order that the bill should be printed, and that then it should not be proceeded with during the present session. He understood that the College of Physicians and the College of Surgeons had no objection to the bill, and that the Apothecaries' Company had only one objection to it. Nearly 30,000 chemists and druggists were in favour of the bill, and it received no opposition from the members of the medical profession. Under these circumstances he wished to know whether the bill could not be proceeded with, and become law during the present session?

Sir G. Grey—The honourable member (Mr. J. Bell) who had charge of the bill wished to make alterations in it, and after the bill, with those alterations, was printed, it would be ascertained whether he was right or not in saying that the bill would give general satisfaction. From what took place on Wednesday, he thought that objections would be made to the bill, but if no one opposed it there could be no objection to its passing this session.

ABSTRACT OF THE BILL.

Clause 1 confirms the charter of the Pharmaceutical Society, except such parts as are altered or repealed in this act.

Clause 2. The council to appoint a registrar and other officers.

Clause 3. The registrar to prepare, from time to time, a list of all pharmaceutical chemists, their assistants, apprentices, or students, respectively.

Clause 4. Registrar to keep books, &c.

Clause 5. Certificate of register to be good evidence in the absence of the contrary.

Clause 6. All members and associates of the Pharmaceutical Society to be registered, also every other person, within one year, on his producing evidence that he was exercising the business at the time of passing this act.

Clause 7. Assistants, apprentices, and students to be registered.

Clause 8. The board of examiners of the Pharmaceutical Society recognized.

Clause 9. The council empowered to make and alter bye-laws, subject to the approval of one of her Majesty's principal Secretaries of State.

Clause 10. Every person examined and having obtained a certificate to be registered.

Clause 11. Power to suspend or modify examination in the case of persons apprenticed before the date of the act.

Clause 12. After one year from the passing of the act it shall not be lawful for any person not duly registered to exercise the business, to assume or use the name of pharmaceutical chemist, &c., or any name, sign, token, or emblem implying that he is registered under this act, under a penalty not exceeding £20, nor less than £2. Penalties recoverable in the county courts, &c.

Clause 13. No proceedings to be taken after the expiration of two months from the commission of the offence.

Clause 14. Penalties to be forfeited to the crown.

Clause 15. Registrar liable to penalty for the falsification of any register, &c.

Clause 16. Penalty for procuring certificate of registry by fraudulent means.

Clause 17. Act not to extend to or interfere with the rights, &c., of legally qualified medical practitioners.

Clause 18. Provided they do not take or use the name of pharmaceutical chemist, chemist and druggist, &c.

Clause 19. Exemption in favour of drysalters, vendors of patent medicines, horse and cattle medicines, or chemicals, &c., used for other than medicinal purposes, such parties not using any name, title, &c., implying that they are registered under this act.

THE NARCOTIC NECESSARIES OF LIFE.

That narcotics have now become a necessary of life to the majority of the human race must be admitted. Tobacco, drugged malt drink, and opium are with many more the *sine qua non* than food and fuel. By way of illustration we copy the following, hoping that it may serve to warn the besotted victims of nicotine that their next step is to morphine. Such persons may boast of their prowess as tobacco-smokers, but if the observations of observing men be correct, they have to boast of very little other prowess:

OPIUM-EATING IN ENGLAND.

Seeing in your invaluable publication of last week a letter soliciting a little practical information as to the best mode of treating a confirmed opium-eater, &c., I beg to offer the following:—It has been my lot to have sojourned for some time in China, which is the hotbed of smoking and opium-eating; and I may say, without vanity, I have had more opportunities than any man of my age in seeing its effects, by prolonged usage, on the sanguineous, nervous, and biliary systems. I then advisedly recommend to withdraw, *gradatim*, the stimulating and soothing doses of morphia, and substitute for it small doses of the tincture of lobelia inflata combined with the tartrate of antimony—these two medicines in combination altering to an extraordinary degree the disorganized condition of the brain and spinal cord; at the same time freeing the liver from its congested state by alterative doses of mercury with chalk, and warm aperient salines. By steadily persevering in this treatment, I may confidently assert, from my experience, that the patient referred to will soon present the "sana mens in sano corpore." I fear your invaluable space will not permit me (knowing as I do the general pressure upon your columns) to enter upon the consideration of the physiological and pathological condition of the nervous system, as induced by the "use and abuse of that beneficial" or deleterious drug, opium, your correspondent simply demanding a practical suggestion.—*Dr. Burnir in Lancet.*

In reply to the question of your correspondent "Medicus," I should say that it is no more "possible to reform a person who has been long addicted to the practice of taking opium," than it is to reform a patient who is paralyzed. Habitual intoxication is as decidedly a disease of the nervous system as paralysis, and as impossible to cure by an effort of volition; or more correctly, it produces a disease of the nervous system almost as intractable as paralysis. Intoxication constitutes a *class* of diseases, of which there are two *orders* and several *genera*.

The two *orders* are *narcosis* and *alcoholosis*, or those produced by narcotic and those produced by alcoholic excitants. The symptoms of these two orders are determined by the kind of excitants to which the patient has been addicted.

That the nervous system is primarily affected, and the parenchymatous structure is subsequently diseased, is so evident, that it requires no proof.

But the point to which I wish to direct your correspondent's attention is, that the two causes of intoxication, the narcotic and the alcoholic, are antagonistic or curative of each other; that, to a certain extent, they stand in the relation of poison and antidote. In delirium tremens from alcohol, for instance, opium is our antidote, and for habitual narcoticism, nothing in the way of remedy is so efficacious as alcohol.

If either narcotic or alcoholic excitants are indulged in exclusively, and in excess, the work of destruction, first of the

functions of the nervous system, and next of the parenchymatous structure, is much more speedy and sure than if both are taken alternately, and in moderation. Hence the poor suffer more than the rich from exclusive narcoticism, because they are deprived of its antidote.

I knew a gentleman of the highest intellect, and of the most fervid eloquence, who took daily twelve grains of solid opium, without sustaining any perceptible injury, either in body or mind. He died in a good old age, in the full possession of his faculties to the last.

It is said of the Chinese opium-smokers, that, to the lower orders, the habit soon proves destructive; but the upper class indulge in the practice with comparative impunity.

As it may not be in the recollection of "Medicus," I would remind him of the case of a gentleman, very similar to that of his friend, which was related in the *Lancet* some time since. In this, as in his case, the habit of opium-taking had been unwittingly acquired. He, too, felt "irritable, dejected, and prostrate in body and mind, and utterly incapable of discharging the ordinary duties and business of life," except under the inspiration of his siren drug, from the allurements of which he found it impossible to escape. But the disease having been developed, volition over it was powerless. In this state, his medical friend, whom he consulted, invited him to dine. After dinner, he plied him vigorously with claret, to the extent of a bottle or more. He had him conveyed to bed, *the worse* for his potation. The patient slept soundly, without his opiate, and awoke next morning, refreshed, and in better health and spirits than he had for a long time enjoyed. The doctor detained his patient as his guest another day, and in the evening he administered another dose of anti-narcotic. The second dose operated equally well, and completed the cure.

It is true that "contraria contrariis et morbi morbis curantur;" but there is a fear lest "incidit in Scyllum, cupiens vitare Charybdim;" but it is also true, that "ubi unica via salutis, ea licet cum periculo est tentanda." It is moreover manifest that there are many more domestic, social, and prudential safeguards against alcoholic, than there are against narcotic intoxicants.—*Dr. I. Pidduck in Lancet.*

SIR C. BELL'S GRAVE AND DR. STEVENS' STUDY.

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—If you think the few accompanying notes, taken from my thoughts during a visit to Sir Charles Bell's grave and to the study of Dr. Stevens, as worthy of a place in your excellent journal, they are quite at your disposal.

I trust the concluding deductions may induce a spirit for research among our talented brethren in the sister isle.—I am, dear sir, yours faithfully, R. TUTHILL MASSY, M.D.

25, Bleuheim-road, St. John's Wood, London,
July 14, 1851.

BELL'S GRAVE.

PERHAPS it may not be uninteresting to the admirers of the great Sir Charles to hear of his resting-place. On the western bank of the Severn, and about four miles north of Worcester, we come to a rising ground, on which stands a large yellow building surrounded with trees, and called Kallow Park. In this house Sir Charles died quite suddenly, and on the evening of the day of his arrival; it is supposed that a rupture of some of the heart's cavities caused this great loss to the medical world, but Lady Bell would not allow an autopsy, and thus we are undecided as to the immediate cause of death.

As we approach the park and ascend the pathway, we see the village church, and in the south-west corner of the yard a few plain tombs are visible, surrounded with iron rails; on one of them the following lines are inscribed:—

SIR CHARLES BELL, K.T.
Born at Edinburgh, MDCCLXXV.
Died at Kallow Park, April xxix., MDCCCXLII.
"Blessed are the pure in heart for they shall see GOD."
This stone is placed by MARTHA, his widow.

To the right of this stone is another, with the records of a Yorkshire banker and his long family; and to the left, over an humble grave, may be seen a weeping ash, that has left its owner's grave and turned to weep over some neighbour. In this county the story goes that it turned over poor Bell, but this is not the case. Now, as I stand contemplating on all worldly honours and reputations, I find myself with the peasant who expected to find a treasure if he reached the golden lines of the rainbow, and, after much toil and perseverance, found it resting on the tomb. Let us not too soon put Bell's kingly work in the grave. His nerves of sensation and motion are not to be interred so quickly: let us have a new theory first. But while I think, the clouds darken o'er me, the thunders roll above, the face of nature is changed, the sun is hidden, the rain in torrents falls about me, and I must get to shelter; the side door of the church is open, and now within it, and almost opposite the entrance, and on the north side of the communion-table, I stand, and before me a white marble stone, plain and unadorned, has written on its surface in black letters those words:—

"Sacred to the memory of Sir Charles Bell, who, after unfolding with unrivalled sagacity, patience, and success, the most wonderful structures of our mortal bodies, esteemed lightly of his greatest discoveries except only as they tended to impress himself and others with a deeper sense of the infinite wisdom and ineffable goodness of the Almighty Creator. He died while on a visit of friendship at Kallow Park."

The records of the past are all around me. The walls are filled with the opinions of those who loved us. No vice is here: all our little virtues are cut out on stone—our wrongs are buried in the tomb. This pretty church is now illuminated with heaven's lightning; the thunders rattle, and the rain still falls, but lighter; and as there is little appearance of a clearing up, I must take you back to Worcester, and get a change of clothes, and remove those wet garments and get my supper, and get to bed, and take you on to-morrow to Dr. Stevens' study, a two-miles walk from Worcester.

STEVENS' STUDY.

Upper Wick House is beautifully situated in a well-wooded park, commanding extensive views. The rippling stream of the Teme may be heard, and Malvere hills may be seen, where all the *pathys* are now progressing—hydropathy, homœopathy, kinesiopathy, and allopathy, and even mesmerism, continuesflourishing.

Dr. Stevens will pardon me for taking you into Wick House, and introducing you into one angle of the mansion which contains a large square room with three windows. You see it is filled with books and papers; journals of every nation, here and there, open and half open: the Book of Books is very conspicuous. He tells me that all his new views are built on the Word of GOD, and not on the word of man; he speaks of his foundation as the house that is built on a rock—ours as the one built on sand.

On this shelf to the left, are books on the blood, books on cholera, books on the salts; and, tossed on chairs and loungers, books on everything, and papers and manuscripts to no end; and then plates on the nervous system in every shape and form. The ganglionic nerves beautifully pourtrayed. Among this confused mass is a little mahogany writing table; by it is seated a fine old man, with silver locks, rolled in an Indian morning gown: the most industrious man living. This is Stevens. His inquiring look and eye almost ask you have you brought anything new. His "how do you do" is quite Scotch, and his unaltered perseverance is also Scotch. He has a great object in view—to prove truth and upset falsehood. For the last four years you might have seen the philosopher here, day after day, determined to shake the foundations of "legitimate medicine" and mere material philosophy, and to raise up a new physiology, and point out our electrical nature, as well as our spiritual state, and to extinguish phrenology, and make all mere materialism vanish before his pen, and a new medicine to shine out of his discoveries! The human mind shall no longer be taught as a material secretion of the brain. This intelligent spirit is not again to be looked on as a glandular secretion, like the tears, the saliva, and the bile; this human mind is not in the cerebrum or cerebellum, but it is just beneath the arch of the tentorium in the third ventricle, in a separate material house of its own, at the root of the pineal gland, and at the upper part of the corpora quadrigemina, at the origin of the optic nerves—the telescopes of the eyes, through which *the mind sees, not perceives*, as the philosophers tell you. Those ideas of Stevens are startling. He tells me that the brain can no more see than a material brick, for it cannot see itself, and that sight is a spiritual gift which is given to the entities that belong to the spiritual world of intelligence; next, that the gray and white matter of the cerebro-spinal system separates the terrestrial electricity from the blood, which electricity the blood has received from the earth by electric attraction. But then he speaks of another electricity contained in the

saline matter of the blood, which produces and keeps up the heart's action, and on those views he has founded his theory of the action of his salines in cholera; and with Dr. Stevens I must confess, that any treatment is preferable to the bleeding, calomel, opium, and other abominations adopted. The extensive bleedings would kill the most healthy and robust, let alone the enfeebled and collapsed, and the repeated dose of calomel must produce debility and secondary fever; and I have no doubt but that the quantities of opium given in fifty cases would produce a sound sleep in five hundred soldiers, and if given to two hundred and fifty, it would close the eyes for ever of at least one hundred and twenty-five.

Dr. Stevens' views, though so distant from ours just now, and so apparently invisible and intangible, are yet deserving of the highest respect, and offer much for our deep consideration. Everything is progressing; we must not stand still, the labours of the disinterestedly industrious must be considered, and not laughed at during the present unsettled state of our art.

I did express my wonder and astonishment when the doctor pointed to an excellent plate on the ganglionic nerves, and, with his fingers on the solar plexus, described it as the seat of life, I felt quite unprepared for such views, yet I see a great deal in them; and if he does even a little good while proving that our minds are spiritual and not material, and that it has its residence in the one central cavity of the head, and that the true life is not in the blood, but originally the offspring of a higher world, and that it has its residence in the central tree of life—the solar plexus. In support of those views, Dr. Stevens refers to many passages in the Bible; then he refers to disease and death in man; and finally, he brings comparative anatomy and experiments on the lower animals to prove his views.

He traces the origin of the pneumo-gastric nerve, *not* from between the olivary and restiform bodies, but from the semilunar ganglion: it is therefore the connecting link between the vital power and the mind. He gives a similar origin to the spinal accessory, and, as he traces its distribution to the root of the phrenic nerve, he tells us it keeps up respiration when the mind is asleep; and then compares those fine cords and the lovely structures within us, with the parts alluded to in those verses:—"Or ever the silver cord be loosed, or the golden bowl be broken, or the pitcher be broken at the fountain, or the wheel broken at the cistern. Then shall the dust return to the earth as it was; and the spirit shall return unto God who gave it."

Bell and Stevens differ widely on some points. For example,

Bell believed that all the motor nerves originated from the brain.

Stevens, on the other side, says that not one of the true motor nerves originates from the brain, or from any portion of the cerebro-spinal system.

According to his views, every one of the true motor nerves of the body originate from *the one central organ of the ganglionic system.*

Bell believed that all the sensational nerves originated from the gray matter of the brain, and conducted sensation from the cerebro-spinal system to the entire body.

Stevens, on the other hand, believes that the vital electricity which is derived from the oxygen of the air that we breathe is the true cause of bodily sensation, and that *the so-called* sensational nerves conduct impressions made on the body, from the body itself to the mental organ, which is in the centre of the head, but not in the brain.

Bell makes the sensational nerves to derive their origin from the gray matter of the brain, and considers these nerves as the conductors of the cause of sensation from the insensible brain to the sensitive body.

Dr. Stevens makes these nerves to originate from every part of the body, and to be the conductors of impressions made on the body to the sensitive mind, which is not in the brain but in its own separate and distinct material dwelling; which impressions give knowledge, which is the true spiritual food of the human mind.

Just now I have not time to enter into his peculiar views on the circulation, and to the many wonderful links in the chain of our creation.

OBITUARY.

At Castleblaney, on the 30th of June, aged 81, George Shegog, M.D., Medical Attendant of Fever Hospital and Constabulary, &c., and for sixty years an eminent practitioner in the county of Monaghan.

NEW ANÆSTHETIC AGENT.—In witnessing some operations performed by Mr. Fergusson, Saturday, June 21, in King's College Hospital, we learned that Dr. Snow was using, with much success, a new anæsthetic agent called chloruretted hydrochloric ether, which Dr. Snow believes had not been administered before, except in an operation in this hospital on the previous day, when Mr. W. Hewett, the house-surgeon, removed some venereal warts from a patient in one of the wards, and applied strong nitric acid to the raw surface. The substance is called by its discoverer, M. V. Regnault, *l'éther hydrochlorique monochloruré*. It is the first of a series of five bodies which he formed by decomposing muriatic ether by means of chlorine gas in the sunshine. A liquid which is a mixture of these bodies, has been used for some months in Paris by M. Aran, a very zealous experimentalist, as a local application to relieve and prevent pain. Dr. Snow having procured a quantity of this through the kindness of Mr. Morson, chemist, of London, separated the first and more volatile of the liquids by distillation, and he thinks that it possesses some advantages over chloroform.—*Lancet.*

DISPENSING OF MEDICINE.

G. OLDHAM AND CO.,

PHARMACEUTICAL CHEMISTS, AND APOTHECARIES,

From BEWLEY and EVANS',

No. 107, GRAFTON-STREET, DUBLIN,

(Corner of Suffolk-street),

BEG to return their grateful acknowledgments to the Medical Profession for the support they have hitherto received, and which they will regard as a fresh motive for exertion. Abstaining altogether from visiting as Apothecaries, except for the application of Leeches, Cupping, and such operations as are performed under medical advice, they will continue to devote themselves exclusively to the duties devolving on the pure Pharmacien.

Having had much experience in Practical Pharmacy, and being resolved to spare neither trouble nor expense in order to have every article of superior quality, they hope by attention, "carefulness," punctuality, and moderation of charges, to commend themselves to the approbation of those who may entrust them with their commands.

☞ *G. O. and Co. invite attention to their present stock of Surgical Instruments, all of which are manufactured on the most modern and improved principles.*

THE ROYAL MEDICAL HALL,

64, DAME-STREET, DUBLIN.

☞ *Change of Proprietorship.*

BEWLEY, OWEN, AND CO., APOTHECARIES,

(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS,

will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT

embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick-room and nursery.

*** GENUINE COD-LIVER OIL,

of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

WHITE'S

SACCHARIZED HYDRATE OF MAGNESIA.

THE attention of the Medical Profession and the Public are respectfully called to this elegant preparation of Magnesia, possessing properties peculiar to itself; correcting the Acid of the Stomach, without causing any apparent disturbance or uneasiness; acting as a mild Aperient; invaluable for Children, particularly at the period of Dentition, its agreeable taste enabling them to take it with pleasure. From its alkaline and detergent property it will be found useful as a Wash for the Mouth, in removing the mucus so troublesome in many Febrile Diseases.

The Manufacturer has Testimonials from eminent Physicians of its value.

Sold at the Medical Hall, 54, Lower Sackville-street; Bewley and Evans's, 2 and 3, Lower Sackville-street; Pring and Co's, 30, Westmorland-street; Mr. William Carroll's, 15, Nassau-street, and also at

JOHN GEORGE BOILEAU and Co.'s,

Wholesale Druggists and Manufacturing Chemists,

26, Mary's Abbey, Dublin,

Sole Wholesale Agents for Ireland.

In Bottles, 1s. each.

TWO ESSAYS ON THE ANATOMY OF THE EYE, WITH FIVE OTHERS IN COMPARATIVE ANATOMY.

Also, 8vo, price 1s.,

ON THE PARALYTIC, NEURALGIC, AND OTHER NERVOUS DISEASES OF THE EYE.

At the Office of the MEDICAL PRESS, 15, Molesworth-street; or Mr. Fannin's, Grafton-street, where Dr. JACOB'S CATARACT NEEDLES may also be had, price 2s. 6*d.*

MEDICAL EDUCATION IN ENGLAND.

PROVINCIAL MEDICAL COLLEGIATE INSTITUTION,

FOR furnishing a complete Course of Practical Instruction, directly bearing on the future Studies of Youths proceeding to the Medical Profession.

In addition to Classics, Mathematics, and the French and German Languages, Practical Chemistry in the Laboratory, Botany, Materia Medica, Osteology, and Figure Drawing will be taught by duly qualified Members of the Profession.

IN CONNEXION WITH THE COLLEGIATE INSTITUTION, TARVIN HALL, CHESHIRE,

For the Education of One Hundred Resident Pupils, under the superintendence and tuition of the following Resident Masters.

Established in 1842.

Principal—John Brindley, LL.D., formerly Second Master of the Grammar School, Brigg; and Head Master of the Oldwinsford Hospital Endowed School, Worcestershire.

Vice-Principal—The Rev. Thomas Waddingham, M.A., late Fellow of St. John's College, Cambridge.

Assistant Classical Master—G. W. Ellaby, B.A., Senior Moderator, Gold Medallist, and Classical Prizeman, Trinity College, Dublin.

Assistant Mathematical Master—Wm. Smart, B.A., Scholar of Sid. Sus. Coll. Cambridge.

Foreign Master—Lionel Banks Penley, formerly Member of the French and German Universities.

Professor of Music and Assistant Foreign Master—Signor Antonio Sapio, Graduate and Associate of the Royal Academy of Music, London; and formerly Pupil of the Conservatories of Paris and Naples.

Commercial Master—R. Keary.

Fortification. Engineering, and Military Drawing—Jos. A. Pease, lately Teacher of Fortification in the Military School, Wimbledon, and to Cadets of the R. M. Academy, Woolwich.

Professor of Chemistry and Experimental Philosophy—James Macaulay.

Botany and Materia Medica—T. C. Archer, Esq., M.R.C.S.

Superintendents of Out-Door Conduct and Discipline—R. Keary and Jos. A. Pease.

Drawing Master—L. B. Penley.

Dancing Master—Mr. Edgar Webster, Chester.

Medical Attendants—Llewelyn Jones, M.D., Chester; Messrs. Earle and Ankers, Surgeons, Tarvin.

The present Vacation will terminate on Tuesday, the 29th July instant.

Tarvin Hall, near Chester, July 1, 1851.

TERMS OF SUBSCRIPTION (PAYABLE IN ADVANCE).

MISCELLANEOUS CASES AND OBSERVATIONS IN THE PRACTICE OF MEDICINE.

By J. Kirby, LL.D.,

Ex-Professor of the Practice of Medicine, R.C.S.I., &c. &c.

FRACTURE OF THE THIGH BONE, WITH UNUSUAL CIRCUMSTANCES—ENGORGEMENT OF THE BRAIN—DEATH—POST-MORTEM EXAMINATION.

A man died some years ago in Jervis-street Hospital. According to the order of attendance observed in that infirmary, he became my patient eight weeks after his admission, and about five days before his death. He was lying without bandage, splints, or pillow: his limb three-fourths of an inch short, but the foot in a proper direction. The seat of fracture presented to the mind the irregularities intelligible by an inspection of the preparation, without any of the surrounding firmness which accompanies a considerable formation of callus. The impression I received from the examination was, that the bone had been broken into three pieces, and although the case had been entered as one of simple fracture in the records of the hospital, I was confirmed in the opinion I formed, and which I expressed to the pupils in attendance, when I was informed that the accident occurred by the passing of a wheel of a cart across the limb while the man was on the ground. The thigh bone and leg were free from œdema and pain, but there was no sense of power of motion. He could draw up the heel and again extend the leg, but when desired to raise the leg and thigh together, he grasped the fracture as if sensible of weakness there. Even thus assisted he could not succeed. I left him as I found him. In two days he complained of some uneasiness in the site of fracture, to which I did not pay any attention, such not being an uncommon attendant on first efforts after confinement for fracture. Two days afterwards the nurse informed me that he had not spoken during the night, and that he could not drink. He was comatose; sweating; fuller quick pulse; eyes open; pupils of natural size; iris immoveable; eyes distorted. Blisters to the neck and legs prescribed, and stimulant glyster, but he died in a few hours. Examining the limb to ascertain the degree of union, before I proceeded to expose the fracture, it was found that the motion of the trochanter harmonized with the rotating motions on the lower part of the limb—a circumstance which we will be able to explain by a reference to the preparation, which I shall now proceed to describe more particularly.

It will readily be perceived that the bone is broken into three parts, and that the spliced piece on the outside, which is very considerable, and extends to the trochanter major, belongs to both the remaining portions of the shaft. The thickest part of these portions acquire half the diameter of the bone, and contain a large share of the medullary cavity. It is united to the trochanteric division of the bone, but in a direction behind its natural level. The line of union exhibited no callus, so that the union has probably been accomplished according to the laws which regulate the most simple and most ready union which takes place among the soft parts of our structure. The inferior portion of the femur lies at the inside of the trochanteric portion, and exhibits a considerable extent of spliced fracture. Thus the trochanteric division of the femur lies between the others as if driven between them; but this relation of the parts is properly attributable to the action of the muscle. There is a distance observable between the external piece and the superior end of condyloid division of the femur. This cavity contained a large spoonful of thick fluid, such as fills ganglionic tumours at the wrist. The membranic cyst which contained and formed it is to be seen; it is thick and opaque, with smooth internal surface, but was more and more transparent where it corresponded with the soft surrounding structure. The separated surfaces of the bone are smooth; the medullary cavity and cellular structure being covered in by a thin but firm osseous plate. The periosteum of the upper piece of the femur is thickened, softened, of a brownish-red colour, and easily detachable, and there is no trace of bony deposition in any of the parts adjoining the fractures, which are separated from each other.

Observations.—From the period which had elapsed, it is probable that the union here was as perfect as it could have been at any future period, or at least that at no period could it be expected that callus, or any thing approaching to it, would have been supplied.

Had reparation been accomplished and apposition been preserved, it is probable that union would have taken place between the parts now disunited, as well as between those in firm junction; the union which has taken place evincing that the bone fully enjoyed its reparative process.

The intimate union above of the large splinter shows the value of close apposition; the inferior fracture displaying the consequences of distinct separation. The intimate union above, without any external callus deposition, strongly evinces the sufficiency of the medullary membrane for the purposes of union, unassisted by any traceable aid from the external investments of bone. The same fact seems to be confirmed by the callus formation which closes up the medullary cavity where apposition is not maintained.

Nature, defeated in her efforts at a thorough repair of the fracture, has prepared a new articulation differing essentially from those which are usually found in instances of imperfect union or false joint, as has come under my observation. The cyst which has been described seems to be a provision for future motion; it is large, undivided by septa, and contained a seemingly bursal fluid, which must undoubtedly have issued as a secretion from its smooth and synovial-looking surface. The firmness of this structure may be fairly appreciated from the firmness with which the parts, even after death, resisted motion made to ascertain the amount of union that had taken place, and which I suspected not to be quite perfect from the uneasiness of which complaint was made on the day but one after he made his first but feeble efforts.

Had he lived it is probable he would have been soon encouraged to try his crutches, and to bear his foot upon the ground. The consequences can be easily foreseen: the limb must have inflamed, and he should return to his bed for an indefinite length of time, and thus have been in the condition in which I found him. Had he borne heavily, was he able to continue these daily efforts, the probability is that a progressive shortening would have been the consequence.

The brain was moderately firm, perhaps somewhat firmer than natural; medullary matter somewhat subsuffused; some effusion subarachnoid; considerable effusion in the ventricles; the scalp, cranium, and dura mater were free from disease. Although there is no evidence that this person was affected by any apoplectic tendency previous to his admission, still I see no reason to suppose that his death was in any way connected with the original injury, or the subsequent condition of the fracture. The nurse, however, remarked that he was asleep since he came under her charge, and one of the pupils informed me that he exhibited unusual insensibility during all parts of the treatment, and that even when there were considerable abrasions from the splints, he did not seem to be aware of their existence; so that there is reason to think that the head was all along engaged, and that disease in that quarter unhappily existed.

CASES OF PRESUMED PHTHISIS—DANGER—CONSULTATION—HOPELESS CONDITION OF THE PATIENT—PRUSSIC ACID—REMOVAL TO THE COUNTRY—DIARRHŒA—UNEXPECTED RECOVERY.

In cases of presumed extreme dangers, when all ordinary means have been prescribed and disappointment has been the result, physicians are willing to catch at any remedy of promise, however personally ignorant they are of its power or efficacy. This is more especially true, if the proposed means are recommended with earnestness and on the authority of accumulated cases, which, coming from a reputable hand, appears to justify the terms in which their virtues are extolled, and for this reason they are thought to have a claim to our notice, and more than that, a claim to our fullest reliance. For this reason, I desire to put these cases upon record. They are pregnant with much information—they show how the wisest may be mistaken, and how accidentally medicines receive a character which they by no means merit.

Some years ago Mrs. W. was by a full consultation pronounced to be in a hopeless stage of consumption. She had a harassing cough of long continuance, copious expectoration, and exhausting night sweats. The appetite was prostrate, while wasting emaciation and loss of physical power were the necessary attendants. Sleepless nights, a feverish pulse, and hectical countenance were in the eyes of her attendants certain evidence of the conclusion which could not be postponed.

As a last resource, it was proposed she should accompany her cousin to Bordeaux, who, being in an advanced stage of phthisis, was recommended to a residence in the vicinity of that town. I therefore concluded my personal attendance to be no longer necessary professionally.

In the evening Mr. W. called on me. He was in deep affliction. He entreated my guidance as a friend, and asked me whether the proposed change afforded any reasonable hope of his wife's recovery. I thought it did not, and I expressed this opinion to him. He resolved she should remain, and then he threw her on my care in these words: "While it is the will of the Lord to spare my wife, give her all your tenderest care, and treat her as you would the person you hold dearest in your affection." This appeal was touching. The confidence thus displayed flattered and embarrassed me while I reflected how perfectly powerless the means of art must be through my instrumentality. Dr. Granville's remedy flashed across my mind. In prussic acid, I saw a new and a promising remedy. I explained the power of the medicine, and I suggested its use; but having no experience in the matter, I was unwilling to prescribe it without his full approbation. He refused the experiment, and resigned himself to a fate which seemed to be inevitable.

Mrs. W. was next day conveyed from her bed into a carriage, and removed to a village near town by my advice. Here her only medicine was dandelion and goat's whey. In a week a profuse diarrhœa set in. At first it seemed to threaten to undermine the slender remains of vital power. Each day, however, was marked by an improvement in strength. To my great surprise, her appetite began to return, while her cough, expectoration, sweat, and feverishness gradually disappeared, and in a few weeks there was no longer any cause for alarm.

Mrs. W. still lives, and although very many years are passed, she presents in her person a striking instance of the efficacy of Nature's doings, and of the helplessness and uncertainty of medicine. Had these events taken place during the administration of the acid, according to a common fallacy in medical reasoning, they would have been attributed to the virtues of the remedy, and a strong case made out to encourage reliance on an agent which experience has amply proved to have no power over a disease in which it was nearly pronounced to be a specific.

The sudden and most unexpected recovery of Mrs. W. must be attributed to the medicinal agency of dandelion and goat's whey,—remedies in very general use by the faculty at the period of her illness. During the long continuance of her tedious disease, her bowels were attended to, so that it is not more surprising where the immense quantity that she discharged was contained, than the effect so rapidly produced by the diarrhœa which supervened. The manner in which this accumulation operated in the production of the severe symptom under which she suffered, I shall not presume to explain; neither shall I attempt any elucidation of that happy issue to which all her complaints were brought so rapidly and unexpectedly; but to me it is quite apparent that an irritation in the bowels was the cause, and that that irritation was owing to whatever was carried off by the catharsis, induced by the dandelion and goat's whey combined.

That Mrs. W.'s case was not one of pulmonary phthisis is quite evident from the rapid recovery, and her being

alive at this day. In the examination of her chest the stethoscope was not used, as it was not introduced into practice until subsequent to the date of the case, so that her illness is to be sought for in that cause which has been just stated.

Nor let it for a moment be doubted that the reason assigned is sufficient to explain the whole train of symptoms, when we reflect on the many instances in which remote sympathies are displayed in consequence of various irritation among the alvine organs. Take all the circumstances, for instance, connected with hysteria, you will find them disappear under a steady course of aperient medicine. I have lately had under my care a young lady in an attack of hiccup unceasingly night and day for a fortnight. She was attended by a physician who tried various and random remedies ineffectually. The case devolved on me. I used every means which my experience or books suggested in this obstinate malady. As her health was good, I advised a journey to a distance of forty miles. Diarrhœa set up as soon as it was accomplished, and the hysteric hiccup at once disappeared.

I have seen another lady in whom an attack of hysteria simulated peritonitis, as it most frequently does. The abdomen was full, and the slightest touch of it gave rise to pain. When the trunk was fixed, and the bowels remarkably costive, when the pulse ranged from 130 to 150, when the tongue was white and the skin was hot and dry. She was the subject of consultation. She was blooded largely. The blood did not buff, and great debility ensued. The disease seemed to be transferred to the head, and coma took place. She was insensible to tickling, to disagreeable odours, to the loudest noise and violent slapping of the hands; the breathing was noiseless and silent, as in syncope; while paleness of the visage and flushing alternated with one another. The urine was secreted in small quantity, discharged with great difficulty, or totally retained. It was unusually clear.

From all these alarming symptoms, she was relieved by a daily use of mild cathartics. A period of consciousness now returns. She describes her pains as at one time better and at another worse, and this in a short period. She describes a painful sensation in the uterus, as of a feeling of motion and enlargement, with occasional bursts of wind from the part. She complained of intolerance of light, and spoke with a slender voice. There was much irregular action of the heart, and she expressed a great desire for solitude. By a continued perseverance in the same mild aperients, she is also relieved from these symptoms.

Frank attributes coughs and catarrhs to such a cause: "Ex ipso adeo *consensu*. abdominali imprimis, non modo tusses, sed ipsos catarrhos oriri, experientia confirmat. Nec certe, cum et oculos, et fauces, et ipsos pulmones, hac a causa non raro incendi sciamus; cum tantam pituitæ sub tussi ferina, cujus sæpe in abdomine origo est, copiam in pectore secerni videamus; mirabimur, sensilissimam bronchiorum superficiem internam a nervis ventriculi, intestinorum per bilem acriorem, suburras corruptas, aut per vermes, continuo irritatis, similia experiri, aut longas vanasque per tusses ad phlogosin ac morbosas secretiones incitari. Hinc ratio summæ interdum virtutis emeticorum, purgantium in catarrhis, præprimis epidemicis, cum gastrica febre manifeste conjunctis, atque adeo spontaneæ, qua non pauci catarrhi solvuntur, diarrhœæ, elucet."

When we reflect on the numerous symptoms of the many diseases of children which yield to the use of purgatives, we cannot but feel confirmed in the opinion, that alvine discharges may alone be sufficient to produce that series of symptoms which induced me to hold such an unfavourable prospect in Mrs. W.'s case, and which disappeared on the supervention of a most profuse and continued diarrhœa.

CASE OF PRESUMED PHTHISIS—SYMPTOMS—DANGER—A FULL CONSULTATION—PATIENT BREAKS FROM HIS ATTENDANTS—ARRIVES AT MY HOUSE—RESULTS OF AN INTERVIEW—DIETETIC TREATMENT—RECOVERY IN FIVE DAYS.

One evening in October, some years ago, Mr. —— of Drogheda drove up to my door accompanied by his wife, who was large in pregnancy, and had not an hour to count on. He was helped into my study in a state of extreme exhaustion.

He informed me that he had been a long time unwell, and had been confined to his bed for some weeks, and under the care of four physicians. His prominent complaints were an alarming debility and emaciation; he had a great cough, with copious expectoration, constant diarrhœa, profuse sweats, sleeplessness, inordinate thirst, with a red tongue, quick pulse, and a continued feverishness. The medical attendants were in serious alarm: his relatives were in despair. It was a question whether he had sufficient strength to bear a journey to town. However, under all risks, it was undertaken. He did not bring any statement from his physicians, who were both surprised and dissatisfied at the resolution he had taken. He answered my questions so fully and clearly, I was pleased not to be embarrassed by such a document. Our interview was long. I saw nothing materially wrong with Mr. F——, so that my questions related principally as to the desires of his appetite and thirst. As he expressed a great eagerness for animal food, I gave my sanction to his wish, and I recommended London bottled porter as the fluid most likely to alleviate his thirst. He rejoiced at the advice, and condemned the obstinacy which forbade an indulgence ardently desired. I ordered five grains of the pulv. cretæ comp., and four Dover's powder, from Mr. Collins in William-street, and then dismissed him to the Londonderry Hotel.

My morning visit found him in bed, after a night of "sound and refreshing sleep, undisturbed by cough, diarrhœa, or sweat." The same diet was continued during the ensuing week; at the expiration of which period he returned to his residence, sufficiently recovered to resume the business of an active occupation.

Now, in a case such as this, of protracted duration and of alarming severity, one may reasonably suppose that all medicines likely to be of service were from day to day prescribed. Had any drug, such as prussic acid, been employed at the same time as these dietetic rules were prescribed, those changes which plainly and almost miraculously followed the adopted regimen, its value would have been extolled, and a dangerous confidence have been reposed in a dangerous and perhaps a worthless remedy.

There was no stethoscopic exploration of the chest. At my first visit my patient was so much better it seemed unnecessary, and every succeeding day there was less occasion to employ it.

This case plainly suggests how much may be accomplished by mere attention to dietetic means in many diseases; nor indeed can we doubt, as Huxham has truly said, that what we administer by ounces and pounds affect us as well as what we take by grains and scruples. If the choice of medicine demands much circumspection, that of diet requires much knowledge of man's living nature, and of the agents to the action of which it is exposed.

Prussic acid has in a great measure shared the fate of many medicines of late introduced into practice, and after a trial, neither scanty nor unsatisfactory, has fallen into comparative disuse, and such is the case with many other remedies. If we look to the history of the materia medica, we find remedies of established value giving way to articles in which confidence has been for a short time most mistakingly and injudiciously reposed.

There is a fickleness by which medical men are led that is a truly dangerous imperfection. It belongs to impatience, the offspring of ignorance, and, as Galen remarks, leads to a disturbance of nature, finally subverting those powers of recovery which nature holds within herself. This fickleness should be avoided by young practitioners, who are apt to think they have a remedy for every disease, if they desire to have established principles of action as they advance in practice.

Case.—On a cold night in February, a few years ago, I was hurried from my bed to visit a lady at twenty-five miles

distance from town. I entered my carriage relying on my servant, whom I desired to bring my large cloak and other muffling suited to that inclement season of the year. He, however, was as forgetful as myself, and I entered the carriage wholly unprovided. I instantly went to sleep. When I reached the first stage I awoke quite chilled, and I started fifteen miles farther. Thus unprotected I again slept, and was so thoroughly starved with cold when I arrived, I begged for some very hot tea before I could see my patient.

When my business was done I felt quite recovered, and returned home in time to make some evening visits of urgency.

I awoke out of my first sleep with many uncomfortable feelings, and I slept no more. I arose at my usual early hour, ate little breakfast, and retired to my study, where I was soon seized by giddiness, a confused feeling in my head, and great debility of my lower limbs, so that it was with much difficulty I got upstairs to bed. I soon fell asleep, but I was disturbed in a short time by a painful starting of all my limbs, and a sensation in my head, as if it were double its size. I felt as if my mind was external to my proper cranium. I conceived correctly, and I answered with my usual promptness, and I made no mistake whatever. While I was recumbent, every article seemed in its place, but as soon as I raised myself to drink, everything appeared to go rapidly round and round me. As the day advanced I was drowsy and easeless. The spasms of my lower limbs increased, ever incessant and painful; sometimes they nearly threw me from my bed. Under these circumstances a medical friend visited me. He ordered a mustard bath to my legs, and some aperient draughts; twenty ounces of blood to be taken from my arm. When my arm was being tied up by my son-in-law, I remarked to him that he would be a cunning fellow to get the quantity of blood desired: that I would surely faint before an ounce was drawn; and I told him he would find my blood to be perfectly cold. Matters turned out as I foretold. My blood was cold to him, and I so quickly showed signs of deliquium as to show him the impropriety of continuing the *evacuation*—his proceeding. The aperient medicine having answered its end, others were substituted. I do not know their nature, but I do the frequency with which I took them without any effect on either my head or my limbs, which continued their severity for several days.

In three days I was the subject of a consultation. After I had answered all questions I expressed a wish to be taken into the councils on my case. I had been now some time ill, and exhibited no marks of amendment, or anything approaching to it. Being asked what I would suggest, I replied, "I had a shilling in my purse, which I would go to market with, and purchase a haddock for my dinner; that I would have it grilled, and that then I would drink a pint of Madeira mulled, and that I was quite sure I would be quite well the next day." My friend laughed at me, and retired to inform my wife that I was at the commencement of the worst typhus fever he had seen. The next visit found me as usual. I suggested my removal to the country, and obtained their consent to go the next day. In the mean time I had my bed prepared, and I started the next day, provided with a chicken and a bottle of Madeira wine. I dined most heartily on my food and a cauliflower. I drank the quantity of medicine, and immediately retired to rest. I perspired copiously, and slept until ten o'clock the next morning, soon after which hour I was to be seen making a visit in West-street.

The distressing symptoms under which I laboured were brought on by the intense cold to which I was so long exposed, and I suffered in my nervous system as many gouty persons do. My attack was one of debility, and hence I foresaw the difficulty of drawing the desired quantity of blood, the deliquium which ensued upon the attempt, and the low temperature of that essential fluid. The abstraction of blood was an error, and so was the sedative course subsequently pursued, together with such strict abstinence for so many days, during which everything was forbidden except the usual diluents. It is quite plain to me that had it been longer pursued, I would have suffered a protracted illness, or some serious metastasis would have taken place. With this view I acted as I did. I knew my constitution, and I felt I was one of those of a peculiarly nervous temperament, that I was suffering very great depression, and that animal food and wine were really and mainly necessary to my recovery. Of the value of this treatment I had subsequent experience. When my head has been affected with pain and confusion, my vision disturbed, and my ears rung with various unnatural sounds, and my heart beat with great irregularity, I have found, in the same course of treatment, relief, without having recourse to bleeding or any depressing remedy.

ACUTE TRAUMATIC TETANUS TREATED WITH CHLOROFORM.

By Richard G. H. Butcher, F.R.C.S.I.,
Examiner on Anatomy and Physiology in the Royal College of Surgeons in Ireland,
Surgeon to Mercer's Hospital,
&c. &c. &c.

James Kelly, aged eight years, was admitted into Mercer's Hospital, under my care, June 29, 1851. The patient not being able to speak distinctly, his mother gave the following history of the case:—On her return home at ten o'clock the previous night, she found the child sitting on the steps at the hall-door waiting for her. He instantly complained of having been beaten and ill treated by some play-fellows, one of whom gave him a severe blow on the throat with a stone three hours before. She also remembered that eight days since a large needle ran into his left heel, and it was instantly drawn out without being broken, but the part continued slightly tender ever since. When she brought him into the house at ten o'clock, she made tea for him, but he refused to drink it, assigning as a reason that "his throat was too sore." Afterwards he was placed in bed and obtained sleep for nearly three hours, when he awoke, and "got a kind of fit, his head was drawn back, and he could not straighten it." At this time the child complained of great pain in the throat, which she attributed to his having got cold from being exposed to the night air. He fell asleep soon again, and remained so for an hour, when he awoke in violent spasms, so violent that "he fell out of the bed quite stiff." He had five returns of the "fits" before he was brought into hospital the following morning at nine a.m.

I saw him immediately on admission. His condition was then as follows:—The jaws were nearly closed, and he could scarcely swallow, owing to the spasm which quickly beset the muscles of the pharynx, yet after much agony and convulsive efforts, the act, however imperfectly, was performed, and fluids in small quantity were got down. The head was forcibly bent backwards, and this condition never entirely relaxed, while superadded, at intervals of a few minutes, were paroxysms, during which there was violent extension and rigidity of the limbs and horrible distortion of the countenance from perverted action of the muscles; the nose being drawn up, the forehead wrinkled both vertically and across; the mouth pursed up, at the same time its angles drawn towards the cheek-bones, forming the most frightful exhibition of the risus sardonicus; the pulse was very rapid, 135 in the minute, and hard and full; the respiration from the very first was performed with the greatest difficulty and accompanied by a sense of agony in the throat, while each effort was attended by a croupy noise; there was profuse perspiration over the entire body, and characterized by its peculiar pungent odour; darting pain shot back from the sternum to the spine, and during the paroxysm the bone was considerably depressed. As the disease advanced, the posterior muscles of the neck were so violently contracted, the head was absolutely drawn down upon the neck, so as to make the larynx and trachea project and stand out very prominently

on the anterior aspect of the neck, and here the spastic action of the muscles almost ceased, for the muscles of the spine were not affected beyond the cervical region, but the muscles of the extremities seriously participated in the morbid action, both the upper and lower being thrown into a rigid state of extension during each paroxysm. The mind in the midst of all this anguish remained perfectly clear.

From the history of this case, there is evidence of the child having sustained injury in two ways from a severe blow of a stone on the throat, and from a punctured wound of the heel; of the latter being the cause of the alarming and fatal train of symptoms, there was evidence from the following fact. On pressure being made over the heel, where only a little black speck marked the point of entrance of the needle, the situation of the wound, the patient was instantly thrown into a paroxysm. An equal amount of pressure applied to the opposite limb produced no sensible effect whatever. This result could be obtained over and over again, rendering the experiment conclusive. The occurrence of the boy having received an injury of the throat brings forcibly to my recollection a case which I saw a few years since. Two young men were boxing, and one received a heavy blow upon the larynx, which broke the left ala of the thyroid cartilage. The day after but one, he was seized with symptoms of trismus, followed by opisthotonos, and he died in sixteen hours, dating from the first stiffness of the neck and difficulty of swallowing to the last expiration.

From the very first the treatment of this boy Kelly was energetic. A large quantity of calomel was got down by the mouth, mixed with a little mucilage and water, and conducted on a spatula to the back of the tongue. The entire abdomen was rubbed over with mercurial ointment, and swathed with a flannel roller, besmeared with the unguent; a quantity was also placed in each groin and axilla. Thus I endeavoured to bring the system under the influence of mercury by internal administration and rapid inunction.

Purgative enemata, largely charged with spirit of turpentine, were repeatedly given from the known fact of the obstinate costiveness which attends the disease, and because we have convincing evidence of their strong revulsive influence on diseases of the cerebro-spinal centre. The occiput and upper part of the spine was freely blistered, and the seat of injury in the heel was incised, and morphia placed in the wound. Almost from the very first the power of swallowing was gone, but every effort was made to get down stimulants, whiskey and water, &c. At first the paroxysms were produced almost every ten minutes, and of the most violent character. I resolved on trying the effects of the inhalation of chloroform on the accession of each. With this intention about a drachm and a half was poured on a warm towel and applied to the nose. The patient never objected after the first two or three trials, but looked rather anxiously for it towards the coming on of the fit. It most certainly rendered the paroxysms shorter and more mitigated in their violence, and lowered the pulse in a remarkable manner. This treatment was continued uninterruptedly to the end. In order to guard against congestion of the brain from the repeated exhibition of the chloroform, I applied eight leeches to the temples and an ice cap to the head. The creature was perfectly conscious all through, and though he could not be cured, his sufferings were greatly lessened. For several hours (nine) before death, the darting pain backwards from the sternum was removed, and the intensity and duration of the spasms of the limbs diminished, while the tension on the jaws never relaxed, and the head remained rigidly drawn back. In this state he died, twenty-four hours after first complaining of stiffness of the neck and difficulty of swallowing, and twenty hours after the accession of the first paroxysm. The patient died quite calmly, not in a paroxysm. The body was removed immediately after death, and I regret to state I could not obtain an examination of it.

NEW PREPARATIONS OF GOLD FOR STOPPING CARIOUS TEETH.

By John Tomes, F.R.S.,
Surgeon-Dentist to the Middlesex Hospital.

If the various operations performed by the dentist were compared, with a view to ascertain the relative value of each, it is probable that the stopping of carious teeth would be placed first on the list. A tooth skilfully plugged under favourable circumstances, is, in point of durability and usefulness, scarcely inferior to one that has not been stopped, or to the tooth had it not been attacked with caries, and needed plugging. Indeed, a tooth which has been well plugged before disease had too far reduced its substance, is in effect restored to the condition of a sound and healthy organ.

If inquiry be made of those who have been accustomed to attend to their teeth, and are somewhat advanced in years, many instances may be found of teeth which have been stopped twenty, thirty, and even forty years; but teeth which began to decay, and yet have remained useful for such lengthened periods without having been plugged, will not be found.

The knowledge of these facts has for many years past led dentists to pay great attention both to the performance of the operation, and to the material most suitable for stopping teeth; and the results of individual experience have been from time to time published.

It may, I think, be safely said that all experienced dentists regard gold as by far the best material for filling teeth, and deprecate the use of any substitute when that metal can be effectively used.

The gold has been used in the form of foil reduced from plate by hammering to suitable degrees of thickness; and in the preparation of this great care and expense have been bestowed. The superiority of gold over all other substances has for a long time been acknowledged; but there are many difficulties in its use, and these require considerable practice and skill to overcome. The gold may be good, and the case favourable; yet, in the absence of dexterity in the operator, the filling may be, and frequently is, defective. Neither will this appear astonishing when the conditions which constitute a good plug are considered in connexion with the position of the teeth, and the parts of these which may require plugging. A perfectly successful plug is a solid mass of gold, fitting perfectly the cavity in the faulty tooth. Hitherto, gold foil has alone been used. This is introduced into the cavity in various forms,—in long strips folded up and down from the top to the bottom of the cavity; in small masses, introduced one after the other; or in small carefully-made cylinders. Whichever method is practised, great care is taken to press the gold against the sides of the cavity in the process of filling, as pressure on the surface of the plug condenses the gold only for a very short distance below the surface. If, for instance, the masticating surface of a molar tooth which has a large hole in it be plugged with gold foil, forced in from the surface, and pressed only towards the bottom of the cavity, it will be found, on removing the tooth, that the gold near the surface has been compressed into a hard scale, while that occupying the bottom of the cavity is porous, and admits of further compression. Hence it has been found necessary to pack in the gold, and in the steps of the process to compress it against the sides of the cavity. When the cavity has been in this manner filled, wedge-shape instruments are forced into the gold, and as room is thus made more of the metal is added, until the instrument can no longer be made to enter the plug. Then the surface of the plug is compressed forcibly with the plugging instrument, the superfluous gold is filed away, and the surface of the plug burnished. Now, if the operation has been conducted in the best possible manner, and the gold used unexceptionable, the plug will be a perfectly solid mass; the foil will have become cold welded. This result has been obtained, and is, perhaps, not very unfrequently obtained by most good operators: but the result would be much more constant if the gold foil having the welding

property could at all times be obtained, and the cavities of diseased teeth were favourably situated for applying the requisite amount of compression. We cannot, however, choose the situation of the cavities; we must treat them in whatever position they occur. But something can be, and, I believe, I may safely say has been, done towards the improvement in gold. A gold has been produced, which, under the pressure of the plugging instrument, welds with the greatest readiness into a solid mass capable of being rolled into plates or drawn into wire.

Platinum is obtained in a spongy condition, is heated, and then compressed in a solid mass: it, in fact, welds as wrought iron does when hammered at a white or welding heat, as it is called. The new preparation of gold may with propriety be called spongy gold, from its close resemblance as regards condition, to spongy platinum. But the gold welds under pressure without the aid of heat.

In 1825, Mr. Caudius Ash obtained a precipitate of gold by using copper, which he thought would do for stopping teeth. He tried it, and did not find that it answered his expectation. The idea was abandoned without further effort. Had he continued his experiments, it is probable he might have obtained a result which would have encouraged him to proceed; and, judging from the success which has attended his untiring efforts in the improvement of mineral teeth, it can scarcely be doubted but that he would have produced a gold similar to that which has recently been presented.

Some months since, a Parisian dentist, on his return through London from a visit to America, brought with him two or three teeth plugged with spongy gold. He called on several dentists—myself amongst the number—and exhibited the stopped teeth. This gentleman also called on Mr. Ash, and offered to sell him the secret of preparing the gold, with directions for its use, both of which he had learned in America. While negotiations were going on, the method of preparation was sold to a dentist for a large sum, and the conditions of sale were considerably raised to Mr. Ash, who then declined the offer.

The purchaser, I am told, found that the gold prepared in accordance with the directions he received did not at all answer his expectations, and he (for the time) abandoned the idea of using it. Mr. Ash, however, recollecting his former experiment, again commenced to work on the subject, and succeeded in producing a preparation of gold which readily welded. Of this he sent me half an ounce. It consisted of a fine brown powder, and of small masses, which readily broke down into powder when pressed lightly. Under the microscope the powder was seen to consist of minute particles of bright metallic gold, in the form of irregular crystals or nodules. Under pressure these minute particles readily unite into a solid mass. Several teeth were plugged, by introducing small balls of the powder and compressing it from the exposed surface of the plug. The results seemed highly satisfactory; but on removing the plug it was found that the welding extended but a short distance from the surface against which the instrument was applied, while the lower part of the plug remained porous, and maintained the brown colour of the powder. This condition indicated a serious imperfection in the method of using the metal, and other plans were tried: teeth were partially filled with the powder, and this was condensed by forcing it towards the circumference of the cavity, thereby forming a solid ring; more powder was then added, and the plug completed. By these means a perfectly solid plug was formed, to which no objection could be made. In practice, however, the use of the powder was attended with considerable difficulty, even though introduced into the teeth in lumps, in consequence of the great waste. More or less constantly escaped into the mouth before its condensation could be effected. In stopping teeth in the upper jaw the waste was very great. It occurred to me that this difficulty could be overcome by wrapping the gold in foil. The experiment was tried, and the result equalled my expectation. By this method I succeeded in making very perfect plugs, which, when removed, presented a solid uniform mass of metal, perfectly welded, and free from pores.

Still the gold seems to admit of improvement—in fact, requires to be produced in the shape of a sponge instead of a powder, so that the present difficulties of manipulation might be overcome, and the use of gold foil rendered needless.

In the *American Journal of Dental Science* for October 1850, the following editorial notice will be found:—"*A new preparation of gold for filling teeth.*—Within the last few weeks several dentists in New York have tested the value of sponge gold, as a substitute for gold foil, for filling teeth; but to what conclusion they have arrived with regard to it we have not been able to ascertain. We have been informed, however, that some are disposed to think very favourably of it.

The preparation is of a reddish brown colour, and readily crumbles into a fine powder on being rubbed; but, on being pressed together, it at once becomes a compact mass. A few weeks ago we received from the manufacturer, Dr. Maire, through Dr. G. E. Haws of New York, a small quantity of it, with a request that we would try it. This we have done; but our experiments have been too limited to enable us to say much with regard to its value. We tried it in the cavity of a dead tooth out of the mouth, and succeeded in making a very solid filling. The surface assumed the colour of gold, and presented a highly polished and beautiful appearance; but, on removing it from the tooth, we found that every other part retained the reddish brown colour of the sponge, with here and there the lustre of a particle of gold. For front teeth this would constitute an insuperable objection. On breaking it, the fractured surfaces had the same appearance. We have also seen two incisors that were filled with it, which were correspondingly discoloured.

It may, perhaps, answer a very good purpose for filling the grinding surface of a molar tooth; but, as it crumbles into powder so readily, we should not think it could be employed for filling a small cavity in the approximal surface of any tooth where the aperture between it and the adjoining organ was very narrow. It is possible, however, that some may have discovered a method of introducing it into the cavity of a tooth, of which we are ignorant; and, as our experiments with it have been very limited, we would be glad if some of our brethren of New York, who have given it a thorough trial, would favour us with their opinion with regard to its value."

The gold here described is probably similar to that prepared by Mr. Ash; but, either from the manner of plugging, or from the quality of the gold, the results seem to have been less satisfactory than those I have obtained. The two subsequent numbers of the journal contain no further information on the subject.

Mr. George, in conversation, told me that he had prepared some spongy gold by making a plate largely alloyed with silver, and then dissolving out the latter metal with nitric acid. In the first experiment he succeeded in producing a gold which formed a good plug; but, in several subsequent trials, he had failed to obtain a similar result.

Some years since I read an account of precipitating gold from its solution by oxalic acid; and on trying the experiment, found that part of the gold was thrown down in a thin sheet. It did not occur to me at the time to use this for stopping teeth; but when the spongy gold was talked of, the experiment recurred to me, and I mentioned the circumstance to my friend Mr. Makins of Kingston, and also showed him the results obtained by Mr. Ash. Mr. Makins and myself were students together at King's College, and colleagues at Middlesex Hospital, he having a short time since held the chemical chair in the school attached to that institution, I knew that, since his retirement from the lectureship, Mr. Makins had been working in metals. At my request he at once undertook to make some researches on the forms in which gold could be obtained, and the results have been most satisfactory.

Mr. Makins has obtained a soft and malleable gold in two forms—one a thin leaf, another a soft compressible sponge.

The leaf has a frosted appearance, which a microscopic examination shows to arise from the surface being minutely nodulated with here and there irregular, imperfect, crystalline columns, arising to a considerable height from the surface of the leaf. If two of these leaves are pressed together, even with an ivory paper-knife, they cannot be again separated. This gold, introduced into a small cavity, condenses under moderate pressure into a most perfect plug; but, if the cavity be large, it must be introduced in small pieces, and each one compressed before introducing another, much in the same way as in using gold foil, excepting that much less care is required as regards the packing and the direction of the folds of metal; for, with moderate care, the whole may be welded into a compact uniform mass.

The sponge is revealed by the microscope to be a porous mass of bright metallic gold. It may be compressed by the thumb and finger to a third of its bulk, or may be torn into small pieces without exhibiting any tendency to fall into powder. The smaller pieces may again be united into a mass by simply pressing them together in the hand. These are advantages which no other form of gold possesses.

The sponge, if the bulk be not too great, condenses into a compact solid mass, when pressed into the cavity of a tooth with the ordinary plugging instruments, and presents a bright burnished surface where the steel instrument has come in contact with it, and a hard frosted surface when it lies in contact with the surface of the cavity. If the plug be sawn through, the interior will be found to be compact, and the angles formed by dividing a cylindrical mass will be found to be sharp and hard. Such a plug made with gold foil may present a similar appearance; but, commonly, the angles will be much less firm, and the plug will fall into several pieces, corresponding to the portions of foil which were separately introduced.

In estimating the relative value of the new forms of gold for stopping teeth, as compared with the gold foil in common use, it must be remembered that the latter has a smooth, more or less burnished surface; that such surfaces weld with difficulty, while the former have nodulated surfaces which have not been burnished or subject to pressure, and that they weld readily; that the foil requires very careful packing, both as regards the position of the folds and their size; while the new gold, from the readiness with which it welds, needs no such care.

The properties of the new and old forms of gold may be shown by taking an equal mass of each, and, with a plugging instrument, pressing them upon the surface of a sixpence. Each will assume the form of a plate; but the foil will break up into small fragments and layers when bent and pressed with the finger-nail; while the sponge and leaf will present a hard rigid mass, which with force may be broken, but it will not fall into small fragments or break up into layers. Again, if the surfaces of two pieces of the new gold which have been pressed against the coin, be placed in contact, and firmly pressed together, they will adhere—a condition which will not be found to obtain with the pieces of gold foil similarly treated. If the surfaces of the plates of the new gold are highly burnished with the stopping instrument, and are then pressed together, they will adhere, but very imperfectly, if at all.

In giving directions for using the new forms of gold, it will be unnecessary to urge the absolute necessity of removing all the softer dentine from the cavity of the tooth to be plugged, and to again state what should be the form of the cavity for receiving the gold, as these points have been fully dwelt on by many writers, and by myself, when treating on plugging teeth, in my Lectures on Dental Physiology and Surgery; for the form of cavity should be similar, whatever kind of gold be used: it should approach a cylinder as nearly as is practicable; and overhanging edges of enamel should, if possible, be removed.

If the cavity be of moderate size, and shallow (for instance, not more than the sixteenth of an inch in depth), sufficient sponge gold for completing the plug may be taken, and pressed with a plugging instrument into the cavity; it should then be gradually worked round the circumference of the cavity with an instrument having a small extremity. At first the pressure should be light, but afterwards it should be increased till the plug is consolidated. At this stage of the operation, the plug (if sufficient of the sponge has been taken) will project above the orifice of the cavity. The surface may now be cut or filed away, and the plugging instrument again used. The gold will probably sink a little under the reapplication of the instrument, in consequence of the removal of the surface which had become so hard that the pressure had not operated through it. The greater hardness of the surface would seem to indicate that the plug is imperfect, from the unequal density in the different parts. It is not so, however. If a piece of brass (or any other metal, indeed,) be hammered, it will in working be found to be harder near the hammered surface than in the interior. Yet the interior will be harder than if the brass had not been hammered, and it will be hard enough. So with a gold plug, if the surface is the hardest, yet the interior will be hard enough, and to the eye will be perfectly compact. Indeed, the hardest part is in the best position,—that exposed to wear. If the cavity be double the depth I have described, then take half as much of the spongy metal as would serve for its completion, and thoroughly compress it, but with as little burnishing of the surface as possible. The cavity will then be in the position of the one I first described, and may be treated in the subsequent stage of the operation similarly. By adopting this plan a more solid plug is gained than if a sufficient quantity of gold for completing the operation had been introduced at once. This method would not be very effective with gold foil, but with the sponge the welding is so perfect, that there is no chance of the upper part coming out or crumbling to pieces: indeed, it is exceedingly difficult to get a plug made with sponge gold out of its cavity, unless by drilling. In this respect it resembles a plug made with amalgam.

If a cavity be broad and shallow, the further side may be first filled by pressing the gold in that direction, before too much pressure has been applied on the surface of the plug. When the further half has been filled, and vertical wall of gold left, the other half may be filled. The two halves of the plug will weld, if in making the wall of the first half, the surface has not been burnished.

An equally good plug may be made by introducing a mass of gold sponge, and, after compressing it moderately, making a hole in the centre, and from this compressing the stopping towards the walls of the cavity. By this method the cavity becomes lined with a cup of solid metal, the centre of which can be readily filled, and the plug made sound.

In large angular cavities, such as are sometimes found in the molar teeth, more especially in those of the lower jaw, a good plug may be made by forcing the gold into the angles: thus reducing the cavity to a cylindrical one. The bottom may then be filled to within the tenth of an inch of the surface, and the remaining part completed. With gold foil the filling the angles of a cavity is often troublesome, but with spongy gold it is an easy matter.

When the compressing instrument ceases to take effect, in fact, when no further consolidation of the metal can be effected,—the plug should project above the edges of the cavity, so that when the surface has been cut or filed away, and further compression is attempted, the plug may not sink below the margins of the cavity.

A sharp wedge-shaped instrument should at this period of the operation be used, and if any parts are found which can be pierced, these should be filled with a little of the leaf gold.

In finishing, all the tool-marks should be removed, the margin of the plug made perfectly level with the surrounding part of the tooth, and with the centre a little elevated. It should, lastly, be brightly burnished.

In using the new forms of gold it is desirable to bear in mind that the surfaces of the metal should be handled as little as possible, otherwise they will become coated with extraneous matter, which will interfere with the welding. Neither should the stock of gold be exposed to the atmosphere. It may be conveniently kept in a wide mouth bottle, which admits of being well corked. Should, however, the metal lose its softness or its welding properties, it may be restored to its former condition by annealing over a spirit lamp.

In selecting the gold for making a plug, I have usually employed the sponge for filling the cavity, and the leaf for stopping the cavity made by the wedging instrument in the partially completed plug.

The two kinds of gold manufactured by Mr. Makins, may, I believe, be obtained of Mr. Ash of Broad-street, Golden-square; and I would urge upon dentists the expediency of giving them a fair trial. At present but little has been made; it is therefore probable that with further experience many improvements in the condition of the gold may be made. But should it be shown that better spongy and leaf gold cannot be produced than that with which Mr. Makins has supplied me, even then I think there is great cause for congratulation, for I believe it will be found that better plugs can be made with these forms, than can, on the average, be made with the gold foil prepared by hammering in the usual manner.—*Med. Gaz.*

MALIGNANT DISEASE OF THE TONGUE—DIVISION OF THE LINGUAL GUSTATORY NERVE.

By John Hilton, Esq., F.R.S.

A female, æt. 39, was admitted into Guy's Hospital for an ulcer of the tongue. It was at first appearance thought to be due to irritation of teeth, but it did not improve after extraction of the teeth, nor from various local applications. On admission there was a large ragged ulcer, with hard everted edges occupying the left side of the tongue, from the tip to the posterior third. She had profuse discharge of tenacious saliva, with intense pain on attempting to eat. There was a gland in the neck somewhat enlarged.

It was Mr. Hilton's intention to remove the disease by excision, but in order to render any operation painless, he determined to divide the lingual gustatory nerve, thus cutting off communication with the brain.

The patient being placed in a favourable position, and the tongue drawn forward by an assistant, Mr. Hilton divided the mucous membrane and submucous tissue vertically, for three quarters of an inch, opposite the molar teeth, over the hyoglossus muscle, and across the upper portion of the sublingual gland.

The operation was much impeded by venous bleeding, but the nerve was exposed and divided. Immediately all sensation was lost in the ulcer, and the anterior portion of the tongue. There was a good deal of pain after the operation on the left side of the face, but leeches and fomentations subdued it. The day after, the profuse salivation had subsided, and food could be taken without pain. Considerable portions of the disease were subsequently removed without pain by ligature, but it was impossible to include the whole mass. Exactly one month from the date of the division of the nerve, she began to feel again, the saliva increased, and the ulcer again became painful. As the disease extended, nothing further was done.

The after-history of the case, given by Mr. George Rose of Yarmouth, is to the effect, that the cervical glands became extensively involved, that the tongue was totally invaded by the disease, became ædematous, that the pains were agonising, and that, as was inevitable, death speedily came to her relief.

Mr. Hilton proposes the question whether the division of the nerve may not be advisable in similar cases, as a palliative.—*Guy's Hospital Reports.*

POISONING BY SCHEELE'S GREEN.

By Thomas Stewart Traill, M.D.,
Professor of Medical Jurisprudence in the University of Edinburgh.

It is well known that various substances capable of acting as poisons are in common use as pigments, and especially that a very beautiful green is obtained from the arsenite of copper, which is commonly known as *Scheele's Green.* An instance of the deleterious effects of this substance occurred here on the 31st of May.

George Webster Graham, a child of three years of age, had obtained some slips of paper coloured with this material, and had chewed some of it. He returned home, complaining of severe pain over his abdomen, and vomited repeatedly. His mother observed some shreds of the paper in his hands, and saw some of the green matter on his lips and cheeks. The vomiting returned at intervals with much severity, the pain was violent, and I was sent for; but I did not return home for three hours after he was taken ill. In the meantime his pulse became feeble, his extremities cold, and face livid. I went immediately on coming home, and found that the vomiting had somewhat abated, and that the skin was recovering its heat; but the pain in the bowels was still acute. On hearing the symptoms I inquired if the child had swallowed anything unusual, heard the story, and, on seeing the piece of paper, immediately concluded that it was coloured by arsenite of copper, and had caused the child's illness.

I instantly gave the only remedies at hand—magnesia in milk, with the whites of two eggs diffused in water—until I could procure the more powerful antidote, the *hydrated peroxide of iron.* I also directed small portions of milk porridge to be repeatedly given. All the symptoms were so relieved before the peroxide was procured, that I judged it unnecessary to administer that antidote, and next morning the boy was quite convalescent.

On the third day the child passed by stool one or two fragments of the paper, on which some of the green colour was still visible, and for a few days more he did not take his food with his usual relish; but no other bad consequence has followed.

I preserved the shreds of paper which the child had carried home, scraped off a portion of the green colour, mixed it with a little soda flux, and subjected it to heat in a tube; when I obtained a distinct metallic crust, with a crystalline inner surface, an alliaceous smell, and resolvable, by heat and air, into white crystals, with triangular facets, proving the colouring matter to contain arsenic, of which the quantity appears much more considerable than I expected. On comparing the pigment on the paper with Syme's Wernerian colours it answers to pale *emerald green* (No. 52).

It seems improper to employ so dangerous a material as *arsenite of copper*, in such large quantity, on articles like paper-hangings, which may often come in the way of children, or other persons little aware of the deleterious properties of this colouring matter.—*Edinburgh Journal.*

DISLOCATION OF THE SCAPHOID BONE OF THE FOOT.

By Dr. Walker, Peterborough.

On the 10th of June, 1850, a stonemason, æt. 40, and of a spare but sinewy form, in stepping from the top of a wall eighteen feet high, to another about a foot lower, over an intervening space of about two feet, advanced his right foot, but stepped short, his toes only resting upon the wall, his whole weight being, in the act of stepping, thrown upon the right leg. The foot, as he says, "bent upwards, and something gave way." Falling down between the two walls, he found himself on the ground on his hands and knees, not hurt, as he conceived, by the fall, but quite unable to work, and his foot in great pain. He was carried home, and Mr. Walker saw him next day. He was in bed, and on examination, his opinion of the case entirely coincided with that of Mr. Hanbury, our excellent house-surgeon,

who had previously visited him. We found a bold projection on the dorsum pedis, in the situation of the os naviculare and a corresponding depression beneath, where, in the normal condition, the tuberosity of this bone forms a distinct projection. Over the displaced bone the skin was tense and red, and over this point there was a deal of pain on pressure. He could bend and extend the ankle-joint without difficulty or much increase of pain. Mr. Walker at first tried to reduce the bone by firm pressure with the thumbs, but it felt firmly fixed in its abnormal position, and he could not move it. He then requested Mr. Hanbury to press the foot downwards, whilst he attempted to return the bone to its position between the astragalus and cuneiform bones, and with an audible snap it returned and the deformity disappeared.

Mr. Walker then merely directed the foot to be kept quiet and fomented; but two days after, finding that the bone felt loose and easily moveable, with a tendency to slip upwards, occasioning the peculiar appearance of a slight dimple or hollow in place of its natural projection, a plaster and roller were applied. He was confined to the house for three weeks. He then returned to his work, but continued slightly lame for a month after. This morning (September 16th), on examination, no remaining appearance of injury is found: he has no pain, and the motions of the foot are perfect.—*Prov. Jour.*

HOSPITAL REPORTS.

ST. BARTHOLOMEW'S HOSPITAL.

Popliteal Aneurism; Pressure; Deligation of the Femoral Artery; Recovery.

(Under the care of Mr. LAWRENCE.)

WILLIAM J——, aged 31, following the occupation of waterman, married, of light complexion, short stature, and habitual good health, was admitted into Bentley ward, January 27, 1851, under the care of Mr. Lawrence. The patient states that his habits have generally been temperate, that he has not overworked himself, and that the only ailment he had had to complain of was an occasional pain in the chest. Seven months before admission, he noticed in the right popliteal space a tumour of the size of a marble which pulsated visibly; the circumstance caused him, however, no alarm, and he was content to rub the tumour with turpentine, without seeking for medical aid. The tumour, however, gradually increased in size, without giving intense pain, and the patient was enabled to attend to his occupation up to two days before admission.

When examined, the tumour was found to be of the size of an orange, situated in the centre of the popliteal space, and presenting very strong pulsations. The hand applied over the swelling received the sensation of a distinct thrill, and a loud bruit was heard on the application of the stethoscope. The patient did not complain of a great amount of pain, neither in the tumour nor in the leg, and the rest of the arterial system seemed in a sound condition.

Mr. Lawrence resolved to try compression of the femoral artery in order to arrest the progress of the disease, and on the 31st of January, four days after admission, a compressing apparatus was applied. It was the usual clamp-shaped instrument, provided with two pads connected with the steel rings (which encircled the thigh without compressing it) by screws of spring materials, the upper part of the screws working as ball and socket. One of the pads was made to press upon the artery in the groin, the other in Scarpa's space, and they were intended to act alternately.

By the use of this instrument, the pulsations of the tumour were completely arrested; the patient, however, stated that the pressure gave him intense pain, and that he should probably not be able to bear the compression long. Nor did his feelings deceive him, for he could endure the apparatus but two hours, at the end of which time it was removed. On the 4th of February, four days after the first application of pressure, Mr. Lawrence proceeded to place a ligature on the femoral artery, the patient having been rendered insensible by chloroform. The artery was tied in Scarpa's space in the usual manner. The pulsations of the tumour ceased immediately and have never returned.

No untoward symptoms whatsoever marked the progress of the case, and so thoroughly did the collateral circulation become established in a short time, that the limb did not sensibly lose any of its natural temperature, though no cotton-wool nor flannel wrappings were used. The patient did not complain of pain in the leg, and he seemed to experience no uneasiness but what might be expected from a common wound in the thigh.

Ten days after the deligation of the vessel there was a little numbness in the foot; the latter was, however, not cold, and the wound in the thigh looked well. The tumour in the ham had now become quite hard; there was no thrill or pulsation to be noticed in it, though the size had not materially decreased. The swelling gradually diminished, however, the patient progressed very satisfactorily, and on the 28th of March, about seven weeks after the deligation of the femoral artery, he was discharged in good condition, the tumour having decreased to the size of a pigeon's egg, and being of very firm consistence.

The only complaint the man had made during the latter days of his stay in the hospital was of tightness and pain in the chest, unaccompanied, however, by shortness of breath. The stethoscope applied to the region of the heart did not afford any bruit or abnormal sound about that viscus.

The failure of pressure in this case seems to point to a more than ordinary irritability of the patient, or to the compression of a nerve or nerves by the pad placed upon the artery. Whatever the cause may be, it shows that this method of treatment (in common with many others), though extremely valuable, and likely, as Mr. Skey states in his work on Surgery, to have a "useful if not a brilliant career," is not universally applicable. Mr. Lawrence's case will tend to show that the various untoward symptoms which sometimes follow the deligation of an artery, can hardly be prevented by the use of external warmth to the limb; but that the temperature is kept up more or less, according to the amount of energy displayed by the vessels which are to carry on the collateral circulation.—*Lancet.*

DEATH FROM A FOREIGN BODY IN THE PHARYNX.

DR. MACKENZIE, at the Edinburgh Medico-Chirurgical Society, showed a specimen of impaction of a foreign body in the pharynx, which had been productive of fatal asphyxia. The parts were removed from the body of a cab-driver, who, while eating his dinner a few days previously, was suddenly choked in swallowing a large morsel of meat. He immediately walked across the street to a chemist's shop; shortly after entering which he fell down in a state of asphyxia. Unfortunately, surgical assistance was not rendered on the spot. He was conveyed a short distance to the infirmary, where, however, he did not arrive till about twenty minutes had elapsed from the occurrence of the accident. Tracheotomy was immediately performed by Dr. Pinkerton, and attempts made to restore animation by means of artificial respiration, but without effect. The foreign body (a large mass, apparently of tough and gristly beef) was seen filling nearly the entire pharynx from opposite the cricoid cartilage below, and projecting forwards as far as the uvula. It rested on the glottis, pressing the epiglottis forwards. The trachea and lower part of the larynx being laid open in front, part of the mass was seen to have entered the larynx, and to have descended a little beyond the *rima*. Dr. M. remarked, that the propriety of using forceps in the removal of foreign bodies from the pharynx, and the danger of employing the probang for this purpose, were well illustrated by the preparation. The use of the probang in the present instance could scarcely by any probability have dislodged the portion of the mass which had entered the larynx, while a single attempt with a pair of dressing forceps would almost certainly have been attended with success. Dr. Mackenzie

showed another preparation, of a somewhat similar kind,—a large piece of meat impacted in and above the *rima glottidis*, and which, in the same way as in the present instance, had produced immediate death by asphyxia.—*Ed. M. Jour.*

A CASE OF POISONING FROM OPIUM, SUCCESSFULLY TREATED BY ELECTRO-MAGNETISM.

By J. B. Biddle, M.D., Philadelphia.

The following case illustrates, I think, very strikingly, the value of the electro-magnetic current as a means of relieving the coma produced by narcotic poisoning:—

At about half-past twelve o'clock of the night of the 28th of April, 1851, I was called to visit a woman, described by the messenger as being in a fit. No history or explanation of the case could be obtained, except that the patient had gone out at about half-past seven o'clock to get something at an apothecary's for a cramp colic; that she had upon her return home eaten her supper as usual, then gone to bed, soon fell into a deep sleep, and finally, at about midnight, from her unusual respiration and the impossibility of rousing her, excited the alarm of her husband and family.

I found her in a state of profound torpor; her breathing extremely slow and interrupted, stertorous and gasping, with spasm of the throat, lividity of the countenance, inability to swallow, utter insensibility to the most violent agitation, pupil contracted to the size of a pin's head, pulse scarcely perceptible at the wrist; in short, all the symptoms of an advanced stage of asphyxia. That it was a case of narcotic poisoning, rapidly approaching a fatal termination, was, I thought, evident, and I at once so expressed myself—the family, however, still professing themselves unable to explain or account for it.

Acting, however, upon this opinion, I obtained the assistance of my friend Dr. Goddard, who lives in the neighbourhood, and the use of his electro-magnetic apparatus; and the doctor, coinciding in my view of the case, we determined, although with no very strong hope of saving the woman's life, to resort to this agent. An attempt was made to introduce the stomach-tube, but was unsuccessful, owing to spasm of the pharynx; and its introduction could have been of no service, as, at the lapse of more than five hours, the poison must have been altogether absorbed from the stomach.

The electro-magnetic machine employed consists of two coils rotating between the poles of two horse-shoe magnets—an unusually large and powerful instrument, producing a rapid succession of violent shocks. One pole was applied to the nape of the neck, the other to the pit of the stomach. For about two minutes after the battery was started no effect was produced. The patient then began to make convulsive efforts with her hands, as if to put away something annoying her, and in perhaps half a minute more she opened her eyes with a ghastly stare. The battery being still kept in action, she rose up in bed, and was able to mutter some indistinct answers to questions put to her.

Upon withdrawing the electric current, the woman immediately sank back into the state of torpor in which I had found her; but as soon as it was renewed artificial vitality was again restored. When the current was a second time stopped, after about the same period of application as at first, the woman continued for some two or three minutes awake, gradually, however, relapsing into coma. After each application of the battery, the interval of consciousness became longer, and at the end of two hours she remained roused for a full half hour, in which she was able to let us know what she had taken.

It appears that she had bought three cents worth of laudanum, and never having taken it before, she supposed it was a proper dose, and swallowed it all. It amounted, as she said, to some three teaspoonfuls — probably two fluid drachms, as this is, I believe, the quantity usually sold for that price. I think it probable that she was also previously somewhat under the influence of whiskey, as we detected it on her breath, and this must have increased the narcotic effect of the laudanum.

We now gave her some volatile alkali and strong coffee, but they were not long retained. After half an hour's consciousness, stupor slowly crept on again, and a further resort was had to the battery, which was followed with rapid, and, as it proved, a final revival.

The patient now got up, walked about, conversed clearly, was able to keep some coffee on her stomach, and it was apparent that she had at last struggled through the effects of the narcotic. Some disposition to somnolence remained, but this was easily overcome without recourse to the battery. I remained with her till half-past four—an hour and a half from the last application of the electricity—and then left her in charge of her friends, directing them not to suffer her to sleep till I saw her again.

Between eight and nine I found her very comfortable, and completely awake, although begging hard to be allowed a nap. Three or four hours natural sleep now took place, and left her completely recovered.

It may be worth mentioning, that in the successive applications of the poles of the battery, while one was kept constantly to the nape of the neck, the other was placed indifferently at the pit of the stomach, the arm-pit, and in the hand; and the effect did not appear to vary.

Since drawing up the notes of this case, upon mentioning it to my friend Dr. Mütter, I found that he had lately resorted to electro-magnetism with success under similar circumstances; and he kindly offered the history of his case for publication with the foregoing:—

"May 14, 1851.

Dear Dr. Biddle,—In accordance with your request, I send a brief outline of the case of poisoning with opium, to which I referred in our interview the other day.

Last spring, my colleague, Professor Pancoast, and myself, were summoned about eleven o'clock p.m., to visit a young gentleman residing at the corner of Ninth and Market streets. On our arrival we found that a large quantity of laudanum had been swallowed accidentally, and although strong and very appropriate means had been immediately taken by several medical students who lodged in the same house, no impression seemed to be made upon the influence of the drug. All the evidences of rapidly approaching death were manifest, and all other measures had been unsuccessfully employed, we determined to employ electro-magnetism. An instrument was accordingly obtained: one pole placed upon the nape of the neck and the other over the epigastrium. Almost on the instant, the muscles of respiration were violently agitated, and the patient sprang up in bed, opened his eyes, and answered questions. The pain in a few moments was so severe that we were obliged to change the position of the poles of the machine. Keeping one steadily applied to the back of the neck, the other was made to touch different points of the thorax, throat, abdomen, and upper extremities. The *burning* sensation occasioned by the fluid was almost intolerable, causing the patient to complain loudly, and effectually preventing any return to the lethargy from which he had so happily been aroused. We deemed it most prudent to continue our efforts, even after the patient was fully restored to consciousness, but I think not more than *an hour* elapsed beween the first application of the remedy and the complete relief of our young friend.—Yours truly,

—*Phil. Med. Examiner.* T. D. Mutter."

REVIEWS AND NOTICES OF BOOKS.

A PRACTICAL TREATISE ON THE DISEASES OF THE LUNGS AND HEART, including the Principles of Physical Diagnosis. By W. H. Walshe, M.D., Professor of Medicine and of Clinical Medicine in University College, Physician to University College Hospital, and Consulting-Physician to the Hospital for Consumption. London. 1851. pp. 580.

Dr. Walshe is already favourably known to the profession by his valuable monograph upon cancer, as well as for an excellent introduction to the physical methods of diagnosis in diseases of the lungs. In the present treatise he has combined the physical diagnosis of diseases of the heart and lungs with the symptoms and treatment of the principal diseases of these organs. The volume consists of two parts; in the first, as he states, "an attempt is made to describe the facts and principles of physical diagnosis in their applications to the lungs, heart, and great vessels." In the second, "the symptoms, physical signs, diagnosis, and treatment of the chief diseases of the lungs, heart, and aorta are clinically described."

"The author's design being to furnish, within a moderate compass, a guide to the detection and treatment of those diseases, he has systematically avoided (unless where some particular object obliged him to deviate from his plan) all inquiries into their general or special pathology."

Dr. Walshe commences with the physical examination of the lungs in health and disease, and describes in succession the results of "inspection, the application of the hand, mensuration, percussion, auscultation, and succussion." In the second chapter, the physical examination of the heart and great vessels is considered in the same order. These two chapters, which complete the first part, and occupy above two hundred and fifty pages of letterpress, may be said to constitute a complete introduction to the physical methods of diagnosis in diseases of the heart and lungs.

The first chapter of the second part, which embraces the individual diseases of the lungs, commences with the following brief notice of "neuralgia of the lung," and "intercostal neuralgia."

"*Neuralgia of the Lung.*—The parenchyma of the lung is not only, under ordinary circumstances, endowed with but slight sensibility, but even in the state of inflammation is very rarely the seat of pain, at least of pain demonstrably referrible to itself. Still the pain has occasionally been noticed in central pneumonia where the pleura had wholly escaped; and various anomalous, and more or less painful, sensations felt by phthisical patients, deeply within the chest, apparently originate within the pulmonary texture. Certain morbid processes in the parenchyma appear then to irritate the branches of the pulmonary nerves.

The only physical condition I have ever succeeded in connecting with these painful sensations (and this only in cases of phthisis) is jerking rhythm of the respiration. The quality of the murmurs may also probably be roughened by their existence.

These sensations are either greatly relieved or altogether removed by counter-irritation, and emollient and anodyne inhalation. They are not so directly, as might be expected, modified by anodynes taken internally."

"*Intercostal Neuralgia.*—The intercostal nerves, especially on the left side, and from the sixth to the ninth, are not unfrequently the seat of neuralgia, which, in respect of diseases of the lung, derives its interest from the possibility of its being confounded with pleuritic pain, and from its being pretty frequently associated with phthisis. The pain is severe, occurs paroxysmally, follows the course of the affected nerve, and if there be co-existent palpitation, may (especially if combined with brachio-cephalic neuralgia) simulate in its paroxysm an attack of angina pectoris. Generally speaking, three tender points may be detected by pressure in the course of the nerve—one in the vertebral groove, another about the axillary region, a third in front, towards the terminal ramusculi. In the female, intercostal neuralgia is often associated with that of the mammary gland, and with spinal irritation.

The physical signs are those of pleurodynia; impaired chest-motion, with weak, jerking respiration, the percussion signs being negative. The three painful points in the course of the nerve, point to the true nature of the affection, distinguishing it from periosteitis, and all pains of intra-thoracic origin.

If the tenderness be extreme at any one of the three points, a few leeches are requisite; subsequently flying blisters will, as concerns local measures, often complete the cure. The endermic use of morphia, and inunction with belladonna or aconita ointments, combined with purgatives, and iron and quinine internally, will triumph generally over the most obstinate case."

In the section upon pneumonia, the author follows Dr. Stokes' classification, and admits four stages of the disease—viz., a stage of "arterial injection; of engorgement; of red hepatization; and of interstitial suppuration." We shall pass over Dr. Walshe's description, and limit our extracts to some of his remarks upon the remedies in pneumonia:—

"In acute sthenic pneumonia there are few barriers to venesection. Advanced age is none; neither do pregnancy nor menstruation, provided the indications be otherwise positive, stand in the way of the use of the lancet. . . . . The earlier the bleeding the better. M. Louis has shown that pneumonic patients, bled within the first four days, recover, *cæteris paribus*, four or five days sooner than those bled at a more advanced period; and Dr. Jackson has proved that by bleeding on the first day, the mean duration, in a mass of cases at the Massachusetts Hospital, was lowered from 14.60, to eleven days. . . . . No fixed rule can be laid down for the quantity of blood to be drawn; the mean amount of four pounds five ounces, taken from his patients by M. Bouillaud, has been most satisfactorily proved by M. Grisolle to have produced no more favourable immediate results (and of the ultimate ones that may not be feared?) than the abstraction of a mean quantity of two pounds seven ounces from a mass of patients treated by himself and others. For my own part, I strongly question the utility of even such amount of depletion as this. Certainly, few cases have presented themselves to me in London practice where it was necessary to draw blood oftener than twice; sixteen ounces sufficing in the first instance, and some ten or twelve in the second. Slow convalescence is not the worst evil in cases where blood has been too lavishly sacrificed; a form of spanæmia is sometimes induced, which it may take months, nay, years, to recover from.

Tartarized antimony stands next in importance to bloodletting in the treatment of pneumonia. . . . . In what manner this important agent produces its beneficial effects on the lung, is matter of the loosest speculation. That it does produce such effects is the really important point, and one of which scientific proofs abound. There is not any available evidence to show positively whether the effects of antimony on pneumonia are more marked when the mineral is (as it is technically called) *tolerated* perfectly or imperfectly; or where it is not *tolerated* at all. The question could obviously only be decided by numerical comparison; and the number of cases in which complete tolerance is observed (that is, total absence of effects on the stomach and bowels), is relatively very small. Improvement often takes place within eight or ten hours after the medicine has been commenced with, and without any notable effect on the alimentary canal being noticed; whereas, recovery also ensues when it acts freely both as an emetic and purgative.

The constitutional effect of mercury is by some held to be peculiarly efficacious in the stage of red hepatization. It is even maintained that when that step has been reached, calomel is a more valuable remedy than antimony. No scientific demonstration of this view exists. If it were correct, the value of antimony, in hospital practice at least, would be singularly small; for the great majority of persons admitted into hospitals have some amount of hepatization when first seen. Mercurials appear to me to be desirable in those cases of pneumonia only where, for some cause or other, antimony is inadmissible."

The subject of phthisis receives the full share of the author's attention which its importance demands, its symptoms and diagnosis being given at considerable length. The section upon treatment contains the following conclusions respecting the use of cod-liver oil in phthisis; in which, from the author's connexion with the Hospital for Consumption, his experience has been very considerable:—

"1. That it more rapidly and effectually induces improvement in the general and local symptoms than any other known agent.

2. That its power of *curing* the disease is undetermined. I mean here by 'curing' the disease, its power of causing, along with suspension of progress, such change in the organism generally, as shall render the lungs less prone to subsequent outbreak of tubercles, than after suspension occurring under other agencies.

3. That the mean amount of permanency of the good effects of the oil is undetermined.

4. That it relatively produces more marked effects in the third than in the previous stages.

5. That it increases weight in favourable cases with singular speed, and out of all proportion with the actual quantity taken; that, hence, it must, in some unknown way, save waste, and render food more readily assimilable.

6. That it sometimes fails to increase weight.

7. That in the great majority of cases, where it fails to increase weight, it does little good in other ways.

8. That it does not relieve dyspnœa out of proportion with other symptoms.

9. That the effects traceable to the oil in the most favourable cases are—increase of weight, suspension of colliquative sweats, improved appetite, diminished cough and expectoration, cessation of sickness with cough, and gradual disappearance of active physical signs.

10. That in some cases it cannot be taken, either because it disagrees with the stomach, impairing the appetite (without itself obviously nourishing), and causing nausea, or because it produces diarrhœa.

11. That in the former case it may be made palatable by association with a mineral acid, and in the latter prevented from affecting the bowels by combination with astringents.

12. That intra-thoracic inflammations and hæmoptysis are contra-indications to its use, but only temporarily so. I have repeatedly given the oil within a day or two after cessation of hæmoptysis without any return taking place.

13. Diarrhœa, if depending on chronic peritonitis, or secretive change, or small ulcerations in the ileum, is no contra-indication to the use of the oil; even the profuse diarrhœa caused by extensive ulceration of large bowel is not made worse by it.

14. That the good effects of the oil are, *cæteris paribus*, directly as the youth of those using it—a singular fact, which probably may one day (when the textural peculiarities of youth and age are better understood) aid in giving a clue to its mode of action."

The second chapter of this part is devoted to diseases of the heart. The author commences with functional diseases. He next describes the inflammatory affections and their effects, followed by an account of the other alterations of its tissue. The last chapter embraces diseases of the aorta, which are considered under the heads "aortic pulsation," "aortitis," "calcification," "coarctation," and "aneurism."

Dr. Walshe's treatise is essentially practical. Avoiding unnecessary details, he has given a succinct though faithful description of every important disease of the heart and lungs; and we make no doubt that the work will be well received by the profession; while it cannot fail of adding to the author's reputation as an experienced physician and an accomplished teacher.

THE LONDON EXHIBITION.

CHEMICAL AND PHARMACEUTICAL PRODUCTS.

This class is divisible into the following heads:—*A*. Chemical substances used in manufacture. *B*. Rarer chemical substances for the scientific chemist; and *C*. Chemical substances used in medicine.

The objects in this class do not admit of more than a general grouping, into the chemicals of the chemical factories, and the more delicate and refined compounds produced in the laboratory. The former of these, inclusive of large specimens of alum, protosulphate of iron (copperas), and soda, are interesting as representing a department of British commerce which has grown into importance within a very recent period. The manufacture, especially of caustic and carbonate of soda on the great scale, has originated and developed itself in a degree almost unparalleled in the history of commerce within twenty or thirty years of the present time. The fires of the kelp-burners on the shores of the islands of Scotland are scarcely now extinct, when vast factories, employing large numbers of individuals, appear to produce in enormous quantities the same alkali, which was until recently scantily derived from the fused ashes of marine plants. The manufacture of this alkali, by an ingenious decomposition of common salt by the simple aid of sulphuric acid, chalk, sawdust, and coal, is now prosecuted to a vast extent for the supply of the industrial arts generally, the quantity used in medicine and pharmacy being comparatively insignificant. At some alkali works fifty and sixty tons and upwards of common salt are decomposed every week, and converted into caustic or carbonate of soda. The alum factories are not less extensive. At those establishments crystallizations on a scale emulating those of nature are constantly in progress. Some very large specimens of these crystals, and of those of other chemical compounds, are placed in the central avenue, some of the masses being eight feet in height. The manufacture of sulphuric acid, and of the compounds used by the dyer and calico-printer, also occupies a prominent feature of commercial enterprise. The prussiates of potash forming large masses of yellow and red crystals, and the green, but perishable crystals of copperas, are illustrations of substances largely used in the arts, and the colours and dyes produced by their assistance, present themselves in every direction, when the classes relating to textile printed fabrics are examined.

Articles.—Decoctions and infusions of medical substances. Superphosphate of lime. Sulphate of lime or gypsum. Fine white sand, found at Todmarton, near Banbury. An extensive and very interesting series of valerianates. Specimens of concentrated medicinal infusions and decoctions, intended to obviate the inconveniences connected with infusions and decoctions as usually prepared. Cod-liver oil, stearine from cod-liver oil, simple and compound extracts of sarsaparilla, English and foreign oils of lavender, benzoate of ammonia, iodide of iron, extract and tincture of Indian hemp, juice of taraxacum, &c. Five specimens of salt, from the Droitwich Patent Salt Works. Mineral paints, which quickly dry under water, and on metals exposed to extreme heat. They are suitable for ships' bottoms, or for damp walls. Sundry paints and varnishes. Carbonate of soda, containing 59 parts soda, and 41 carbonic acid, particularly adapted for scouring wool or woollens, as it removes grease without injuring the animal fibre. Refined oil. Pure oleine, for watches, clocks, chronometers, fine machinery, and instruments; free from acid or mucilage; not affected by change of temperature, and having no chemical action on metals. Colours manufactured from the oxide of zinc, applicable for painting in distemper, on porcelain and boards, for paper staining, and for oil-cloth. The qualities of these paints are stated to be their freedom from noxious properties, their permanency, and economy. They are not acted upon by gases. Specimen board painted with various colours in zinc paint. [Oxide of zinc is stated to be the basis of the various paints (browns, yellows, reds, blues, greens, white) in this collection.] Crystal of copperas, or sulphate of iron. Arran kelp, muriate, nitrate, chlorate, and sulphate of potash. Sulphate of soda, pure sulphur, commercial iodine, pure sublimed iodine, iodide of potassium, iodide of lead, biniodide of mercury. Preparations from seaweed. Semola; caffeine; kreatine; kreatinine; uric acid; allantoin; hippuric acid; urea. Cantharides *(Cantharis vesicatoria)*, imported from Russia. Cantharidine, the active principle of cantharides, alone (in three states—viz., from solution, by sublimation, and fused) and in combination with bases. Cantharidine and potassa. Cantharidine and soda. Cantharidine and oxide of lead A pyramid of best table salt, with several other specimens of salt. The salt springs in Cheshire are the greatest in Europe, and their annual production is upwards of 800,000 tons of salt. Specimens of deeds, writings, books, maps, engravings, &c., injured by fire, water, age, dirt, smoke, mildew, water, &c., in a restored and unrestored state. Those with red lines round them were taken from the ruins of the great fire at Lincoln's Inn, Jan. 14, 1849. [Specimens of parchment documents, leaves of books, &c., which have been injured by fire, &c., are exhibited with one-half of them restored without separation from the injured portion. The unrestored part is hard, horny, and brittle; the restored portion clean and flexible.] A chemical liquid for imparting the colour of mahogany and rosewood to common woods. A specimen of the prepared wood, polished, with a bottle containing the liquid; the sides of the block are left unstained, to show the natural wood. [The liquid commonly employed for staining wood, so as to communicate to it the appearance of antiquity, is a caustic solution of potash. The same effect is also produced by the use of soap leys, simply in consequence of the free alkali contained in that liquid. Other chemical fluids are likewise used for the same purpose.] Mineral substances used for the manufacture of paint; in their natural state and pulverized. Iodide of iron, saccharated fifty per cent. in brilliant lamellæ, neutral and soluble, remains unaltered by the air; iodide of quinine in a neutral crystalline form; iodide of quinine and iron, in the form of syrup; iodide of iron, in the form of syrup; iodide of lead, crystals. Chloride of lead, crystals. Citrate of protoxide of iron, powder. Ammonio-citrate of protoxide of iron (lamellæ). Citrate of sesquioxide of iron in lamellæ. Ammonio-citrate of sesquioxide of iron (lamellæ). Quinine, neutral sulphate, crystals, soluble. Citrate of quinine and iron, neutral soluble. Phosphate of iron, soluble lamellæ; phosphate of quinine and iron, soluble lamellæ. Benzoic acid, crystals. Caffeine, crystals. Hydrochlorate of morphia, crystals. Collodion, liquid plaster. Nitrate of silver, crystals. Fluid extract of dandelion, prepared by spontaneous inspissation of the pure juice. Solution of bimeconate of morphia entirely free from narcotine. Preparations of cotyledon umbilicus.

Cod-liver Oil.—Thinking it owing to its non-absorption, that the oil sometimes appeared to lose its efficacy, M. Loze, a naval surgeon, combined it with a mucilage containing pancreatic juice, which thus forms an artificial chyle. He states it to be thus completely and readily absorbed, and in phthisis its effect more directly obtained.

HOUSE OF COMMONS—Thursday, July 24.

MEDICAL CHARITIES (IRELAND) BILL.

The house went into committee on this bill—Mr. Bernal in the chair. On the 6th clause being moved,

Mr. Reynolds moved the following proviso:—"Provided always, that to every dispensary district and other charity, where only one medical officer shall be appointed, every such officer shall be required to possess the qualification of either physician and surgeon, or of apothecary and surgeon."

Sir W. Somerville opposed the proviso.

Mr. Whiteside supported it.

A desultory discussion ensued, in which Colonel Jones, Mr. Scully, Colonel Dunne, Mr. Hamilton, Mr. Sharman Crawford, Sir Lucius O'Brien, Lord Naas, Dr. Power, Mr. Napier, Mr. Hatchell, Mr. Roche, Mr. Clements, Sir D. Norreys, and Mr. Vesey took part.

Mr. Wakley thought that nothing more was required than a proper qualification. He granted that the medical men in Dublin, physicians and surgeons, were very eminent, their examinations were most searching, but they knew nothing of pharmacy, and in every case where a medical officer might be appointed to one of those charities, he should at least be a surgeon. When he (Mr. Wakley) was in Ireland, he observed that the poor people there wanted food, and not physic; and in all his experience he must say, that a people more industriously disposed, or more forbearing, he had never known. Should the bill pass in its present shape, it would exclude from those charities a most valuable class of medical officers.

Mr. Reynolds said that a great distinction was to be made between the apothecaries in Ireland and the apothecaries in England. An apothecary in Ireland, for instance, had a knowledge of surgery, but in England, an apothecary was quite hedged in, and thoroughly innocent of the art of surgery, and with respect to your mere surgeons, he would as soon hand the poor over to any "scientific butcher" as to one of them, who was unacquainted with the art of compounding medicine. If the bill should pass in its present state, it would have the effect of ignoring 2,000 educated apothecaries in Ireland from filling medical situations.

The committee, after a few words from Dr. Power, Mr. Roche, and other honourable members, divided, when there appeared—

For the proviso	6
Against it	66
Majority	—59

Mr. Hamilton moved the following amendment:—"At the end of clause six to add. Provided always, and be it enacted, that in making any order or any rules and regulations touching the qualifications of persons eligible to fill the offices of medical attendants to any dispensary, hospital, or infirmary under this act, it shall be lawful for the said commissioners, and they are hereby required, to call in the president of the King and Queen's College of Physicians, and the president of the Royal College of Surgeons, Ireland, for the time being, and in all matters touching such order or rules and regulations respecting the qualifications of such medical attendants, but on no other, the said presidents respectively shall have a vote, and shall have equal authority with each of the said commissioners as aforesaid."

The amendment was negatived without a division.

Colonel Dunne was opposed to the retention of clause 6 altogether. One of the great objections to the bill on the part of the Irish members was, that it would give a great deal too much power to the poor-law commissioners—a body in which he had no confidence. He had at all times an objection to centralization, and of all centralization he thought that centralization in the hands of the poor-law commissioners was the most objectionable. He should, under all considerations, move for the expulsion of the clause. The bill gave the power of taxation to the poor-law commissioners, who had in various instances abused that power, to the great injury of the taxpayers of the country.

Mr. Roche was of opinion that a centralizing authority was necessary, and that the government was the party who should have that centralizing power. A change in the system of the medical charities in Ireland was necessary, and he was apprehensive if his honourable and gallant friend's amendment should be carried, that it would endanger the bill altogether. He must therefore object to the amendment of the honourable and gallant member.

A discussion ensued, in which Lord Naas, Mr. Hamilton, and other honourable members took part, and which terminated in Col. Dunne consenting to withdraw his amendment.

The clause 6, as amended, was then ordered to stand part of the bill. In clause 7

Mr. Vesey moved an amendment to the effect, that an annual subscription of £1, or a donation of £10, to any of the medical charities to be established under the bill, should entitle the donor or subscriber to serve on the committee of management.

Sir W. Somerville opposed the amendment, on the ground that it would destroy altogether the superintendence of the board of guardians over committees.

A discussion ensued, in which Lord Naas, Mr. Hamilton, Mr. Scully, Mr. Hatchell, and other members took part.

Colonel Dunne said that taxation in Ireland for the support of the dispensaries amounted to nearly £200,000 a year. He thought that the bill ought to contain a provision for a committee of management to be chosen from the ratepayers, the operation of which would have the best effect.

Mr. Cornwall Lewis opposed, and Mr. Sidney Herbert supported the amendment.

Mr. Sharman Crawford was of opinion that the working of the voluntary system in Ireland had led to great jobbing, and ought to be abolished. If gentlemen in Ireland were anxious for a continuance of the voluntary system, they were at liberty to establish that system on their own account; but it appeared to him desirable that it should be abolished.

The committee then divided, when there appeared—

For the amendment	27
Against it	38
Majority	—11

Colonel Dunne, in clause 7, moved an amendment proposing to give to the ratepayers the power of electing the committee of management.

Sir W. Somerville, after a few words from Sir Denham Norreys, opposed the amendment, as one which in its operation would draw into action the whole machinery of poor-law officers—a course which would be attended with great expense. He must oppose the amendment as unnecessary.

Mr. Roche also opposed the amendment.

The amendment, after a discussion, in which Mr. McCullagh, Mr. Hamilton, and other honourable members took part, was withdrawn, and clause 7, as amended, was ordered to stand part of the bill.

Clause 8, as amended, was agreed to.

Lord Naas considered it improbable that the bill would be passed into a law this session; and therefore thought that the most desirable course was to postpone the further consideration of it until next session, when they would have the whole subject of the hospitals of Ireland before them.

The Chairman was asked to report progress, and to ask leave to sit again. He did so.

The house then resumed, and at three o'clock adjourned.

The following letter from Sir W. Somerville to a member of the House of Commons, was read at a meeting of the medical men of Cork on Saturday the 19th instant:—

London, July 15, 1851.

My dear Sir,—It is impossible to foretell the fate of the Medical Charities' Bill; but as regards the support of existing institutions, the safe course will be for parties interested in their preservation to subscribe as usual, and as if there were no medical charities' bill in contemplation. Dr. Corbett is quite in error when he says that I declared an intention of reducing the number of dispensaries by one-third. I was asked if I had formed any estimate of the probable expense under the new bill? What I said was, that if the country were to be equally divided, and average salaries apportioned, my calculation might approach to correctness; but we know that this is impossible. There must be great inequalities, both in the size of the districts and in the amount of salary to be paid to the different medical attendants, and it is impossible to say to what extent these inequalities might reach. If Dr. Corbett means that the existing number of dispensaries should be arbitrarily maintained, or that the medical attendant of any discontinued establishment should be compensated (I suppose he means pensioned), I feel satisfied that the House of Commons would listen to no such proposal; and it should be remembered that, at the present moment, the dispensary physician is only maintained by subscriptions, which are fast failing in many localities, and which, in too many instances, I fear, are only kept up by a resort to contrivances, from which the medical profession, for which I have the highest respect, will be totally relieved by the provisions of my bill.—I remain, my dear sir. faithfully yours,

W. H. Somerville.

MEDICAL CHARITIES' BILL.

The bill has at last passed through committee, but to apply to dispensaries only, and was to have been "reported," by special leave of the house, on Monday evening. The precise changes cannot be with certainty stated, but they are to this effect:—In clause 8 the appointment of surgeons is given to the committees of management, and not to the guardians. Clause 9, providing power to grant medical relief, was passed. Clauses 10 to 19, providing for the establishment of district hospitals, were struck out. In clause 20, the provision securing the salaries of infirmary surgeons to present incumbents, passed, but takes it from their successors. Clauses 21 to 34 passed. An effort was made to secure the establishment of district fever hospitals, but it was found impracticable.

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, JULY 30, 1851.

We have been from time to time taunted with the charge of remaining silent spectators of the conflict between the Government and the advocates of Irish interests touching the parliamentary grants to the Dublin Hospitals; and sundry letters, without name of writer, have appeared in the papers, inquiring, with somewhat of a sneer, why the College of Surgeons "made no sign" on the occasion; at the same time insinuating that all this has arisen from certain leanings to a policy, having the care of one's self for its object. In this there may have been some truth. We have fallen upon peculiar times, and find that we have cattle to deal with who have unconsciously displayed a signal which warns us not to run right on their horns. A little caution, too, has become an essential ingredient in the tactics of those engaged in operations against an enemy while doubtful allies are hanging on their flank. The result has fully justified our reserve, and proves to us that if we had allowed ourselves to be cajoled into a premature advocacy of these parliamentary grants, we should have fallen into a trap, and become involuntary accomplices in an undertaking we could not defend. The "murder," in fact, is out. The Government, while it takes credit to itself for not withdrawing the whole of the grants, confines its bounty to one hospital, throwing over all the rest: this hospital being one of the streams of patronage by which the soil of Ireland is irrigated. The Chancellor of the Exchequer, with matchless command over his facial muscles, tells his English adherents in the House of Commons that the grant is restricted to this hospital because it is "the main school of medicine in Dublin:" a statement utterly untrue, as every one of our readers well knows. In fact, it is not a school of medicine or surgery at all: it is a general hospital, where students "walk" the wards as part of their educational exercises. We do not mean to say that Sir Charles Wood has intentionally stated what he knew to be untrue, however the person who instructed him has done so; but we mean to say that he must well know that this hospital is thus selected because the appointments of its officers are made in Dublin Castle. But this is not all. It is now as notorious as the sun at noon day that the scheme contemplated is the rendering this hospital a crutch to prop up the crazy political fabric called the Queen's University. It is, in fact, the foundation of Queen's University Hospital in Dublin. And why not? will say the fortunate objects of Viceregal favour. No reason in the world except this, that a proceeding so manifestly affecting important interests, both public and private, should not be carried on secretly, craftily, and by side-wind; but openly, honestly, and by direct means. If the Government takes into its hands the education and licensing of medical practitioners, so be it; but let not the British parliament be told that money granted for the purpose is a charitable offering to Ireland. We utterly abhor the mixing up o our profession and its institutions with political manœuvres, and above all things abhor any entanglement in the present politico-religious warfare; but if the State is to dabble in our affairs at all, let it take the whole responsibility, care, and expense which such a course must entail. In Dublin, surgical education is conducted strictly on the voluntary principle; neither the College of Surgeons nor the private schools recognized by it receive one shilling of public money, and yet with this fact before its eyes does the Government erect rival institutions. With such a competitor there is no contending, and therefore do we say that if it must be so, the Government should take the whole department into its hands, providing for vested interests and granting compensation for losses. Persons who do not choose to be informed on this subject will say, what has all this to do with the grants to the hospitals? but those who are familiar with the working of Irish political machinery will understand us. These grants, at their present amount, and in their present shape, it is obvious must sooner or later be reduced, and more fairly and judiciously distributed; that to the old poorhouse, or House of Industry, especially, cannot be defended; but as the principle of devoting them for the maintenance of educational hospitals has been conceded and acted upon by the Government, the question arises as to the fairest and most useful distribution. As long as the fortunate participators in these grants were able to hold them, we refrained from urging the justice of an equitable division of the sum voted by parliament amongst all the educational hospitals; but now that a monopoly is threatened it is high time to interfere. Let every recognized hospital have a share, proportioned to its present means of accommodation, and we will answer for the result: all that is required is so much sacrifice as will secure unanimity. We care little for the grumbling of John Bull, as expressed in the following fashion. If he does not like our terms, let him send the Queen to Dublin and take a Lord Lieutenant in London in her place:—

A discussion took place in the House of Commons on Tuesday, the 15th inst., in reference to the propriety of making annual grants of money for the support of certain hospitals in Dublin. The discontinuance of these grants had been recommended by a parliamentary committee, and the feeling of members was so far in favour of this view, that the proposition to continue them was rejected by a majority of 63,—the numbers for and against being respectively 43 and 106.

The Chancellor of the Exchequer stated that "it was not true that the whole of them had been stopped, and in the grants to the Richmond and Hardwicke Hospitals, which were the main schools of medicine in Dublin, there had been no diminution. He should be sorry that, for the sake of a small grant, the schools of medicine in Dublin should be allowed to fall into decay; and this perhaps formed a ground why the case of some other of the hospitals should be considered. The house must remember, however, that there were no similar grants to the hospitals of this country; and as far

as the majority of them was concerned, he saw no reason for differing from the opinion of the committee."

When the case of the other Dublin hospitals is considered, we trust that some of the English and Scotch schools of medicine and hospitals will come in for a share of the public money. All that is wanted is "justice to England and Scotland." Either support equally in the three kingdoms, hospitals and schools which really require grants, or abandon the principle of supporting such institutions in any one country.

Mr. Grogan, an Irish member, observed—"If those grants were withdrawn, one of two alternatives must occur, either the hospitals must be closed, and the medical schools be destroyed, or the citizens of Dublin must themselves maintain them; and when it was considered that not 50 per cent. of the patients were in any way connected with Dublin, that was a hardship which they ought not to be called upon to bear."

We would just ask Mr. Grogan to consider how the London, the Middlesex, Charing Cross, and the new St. Mary's Hospitals are supported. The citizens of London maintain them, and why should our government take away from the citizens of Dublin, by annual grants of the public money, the opportunity of following the noble example which is thus set to them by the inhabitants of London, not merely to support their own sick, but the sick from all parts of England? This is certainly a new and singular method of carrying out the system of 'protection.' The English citizen, who pays one-tenth of the whole revenue of the united kingdom in the form of income-tax, is expected by Mr. Grogan not only to support his own charitable institutions, but to pay for the support of other charitable institutions in a country where the income-tax is unknown! In many of our schools of medicine the professors do not receive sufficient to pay their expenses, and in very few instances can it be said that they receive a fair remuneration for their labours; we trust, therefore, we shall hear no more of these one-sided propositions to support institutions which ought to find the means of supporting themselves.—*Med. Gaz.*

We pardon our contemporary for these remonstrances, because he is entirely ignorant of the true state of the case. No school of medicine or surgery receives one shilling of public money; and of the six recognized surgical hospitals, three only receive a portion of this grant. The largest item of the sum is for the old poorhouse of Dublin, some ten thousand pounds, out of which is carved the grant for the hospitals under government patronage: one a surgical hospital, another a fever hospital, and a third called a "chronic" hospital; originally, we believe, a kind of incurable hospital. This is the concern Sir Charles Wood told the house constituted "the main schools of medicine in Dublin," a concern which can scarcely be said to be in Dublin at all, being some two miles or so from the College of Surgeons and the University, and located in a remote, deserted, and dilapidated quarter of the city. We may presently have some talk with our learned brother of Cockneyland on the comparative claims of England, Ireland, and Scotland on public support for institutions of this description; and he in the meantime will, perhaps, inquire how much of the public money is given to Scotch colleges, and how much of crown lands and church lands constitute the principal resources of the great London hospitals. As to setting down these new conciliation colleges and their university to the credit of the medical profession in Ireland, we utterly protest against it. As we have already said, the whole affair is, from beginning to end, a rank Irish political job, and that, we believe, is saying enough for it.

OBITUARY.

July 17th, at Cookstown, Samuel L. Potter, Esq, M.D.

July 21st, Patrick Clinton, Esq., M.D., Fellow of the King and Queen's College of Physicians in Ireland.

A FIVE-SHILLING DOCTOR.

THE LAW OF QUACKERY.

On Tuesday, the 15th inst., a fellow named Edward Maher was arraigned before Judge Moore, who presided in our county court, for practising as a quack doctor, inasmuch as that he, on the 2nd of December last, defrauded Mary Neale of Davidstown in the sum of five shillings under the pretence that he would cure her in lieu thereof, of spitting of blood, with which she was affected.

His Lordship inquired if there was a precedent for a prosecution of this kind?

Mr. Sausse, Q.C., replied in the negative.

Judge Moore—Could a doctor who undertakes to cure certain diseases which he is not competent to do be indicted for his inefficiency?

Mr. Sausse—Maher alleges that he can cure all kinds of diseases.

Judge Moore—The best and worst doctors in the land allege the same.

Mr. Scott, Q.C.—The prisoner has been going about through the country, raising money from the credulity of the poor deluded people, who trusted to his skill in the healing art.

Judge Moore—But I apprehend that the case is unstable and wants a fact. The prisoner having falsely pretended does not furnish sufficient grounds to warrant a conviction, and unless you can show that the prosecution will be successful, I think it is better for the sake of the public morals—from the nature of the evidence that should be elicited—that the case be dropped.

Counsel for the crown having acceded to the recommendation of the court,

His Lordship, addressing the modern Esculapius, said—You have been placed in that dock for having obtained money under the false pretence of curing innocent, confiding people of certain diseases. I have thought it right for special reasons to order your acquittal in the present instance; but if you continue to follow your wicked course, you will most assuredly have to pay the penalty sooner or later. Had the poor woman, Mary Neale, lost her life through your vile instrumentality, the consequences to you would have been of a very serious character indeed.

AN UNUSUAL FORM OF TUMOUR.

Dr. Bennett exhibited to the Edinburgh Physiological Society, the half of a fibrous tumour, which, when entire, was somewhat larger than a billiard-ball. It was found loose in the cavity of the peritoneum by the late Dr. John Reid, who has described it in a paper inserted in the *Edinburgh Medical and Surgical Journal*. He observes, "With the exception of a few depressions, it was perfectly round and smooth. On making a section of the tumour, it was found to consist of a number of concentric laminæ, with a calcareous deposit in the centre. It was very elastic; and the fresh section was exactly similar to the fibro-cartilage placed between the bodies of the vertebræ,—with this difference, that the centre of the intervertebral substance is soft and pulpy, while the centre of the tumour was occupied by the calcareous deposit."

On making a thin section of the so-called calcareous deposit, it was ascertained by Dr. Bennett to present a remarkable organic structure. This was exhibited to the society under the microscope, and presented a cellular structure, closely analogous to what was observable in the pith of phanerogamous plants. The cells varied in size, from the one-thousandth to the one-five-hundredth of an inch in diameter, round in the centre, more compressed at the edges, and presenting a broad rim which was loaded with mineral matter. Here and there, dense partitions, resembling in structure compressed woody fibre, passed through the mass of cells. It was clear, from this description, that the hard nucleus of the tumour was not composed of a plum or apricot stone, to which at first it bore a considerable resemblance. Could it be the branch of a tree, which had been swallowed, ulcerated through the intestines, and formed the nucleus of the tumour, which at first united, had afterwards become detached from the peritoneum? Mr. Quekett, to whom Mr. Bennett had shown the preparation, considered the texture to be cartilaginous; but he was by no means satisfied of the correctness of this opinion.—*Edinburgh Monthly Jour.*

TO THE MEDICAL PROFESSION.

JOHN GEORGE BOILEAU AND CO.,

In introducing to the notice of their Medical Friends the quality of their Cod-liver Oil, which they can guarantee as perfectly genuine, beg also to call their attention to their stock of Drugs and Chemicals, which, upon inspection, will be found of most superior quality. We also beg to introduce to the notice of our Medical Friends, especially those connected with Public Institutions, that they can be supplied with all Druggists' Sundries and Medical Appliances, such as Glass Bottles of every size, Trusses, Pill-boxes, &c. &c.; and have the gratification in stating that we are at present supplying some of the largest Public Institutions in Ireland.

Wholesale Druggists and Manufacturing Chemists,
26, MARY'S-ABBEY, DUBLIN.

CHLOROFORM IN SURGERY.

This day is published, price 1*s.* 6*d.* in Cloth, or 1*s.* in Paper Wrapper,

REMARKS ON THE APPLICATION OF CHLOROFORM TO SURGICAL PURPOSES.

By CHRISTOPHER FLEMING, M.D., M.R.I.A.,
Formerly Lecturer in Surgery in Park-street School;
Examiner in Medicine and Surgery in the Royal College of Surgeons in Ireland;
Surgeon to the Netterville Hospital.

Dublin: Hodges and Smith, Grafton-street.

QUALIFIED SURGEONS FOR SHIPS.

THE London and Provincial Medical Protection and Benevolent Society, 43, Lincoln's-Inn-Fields, London, provide Emigrant and other Ships with Medical Officers. Gentlemen desirous of obtaining appointments may be provided with particulars by communicating with the Liverpool Agent, Mr. William Webb, Union Court, Castle-street, Liverpool.

THE ROYAL MEDICAL HALL,

64, DAME-STREET, DUBLIN.

☞ *Change of Proprietorship.*

BEWLEY, OWEN, AND CO., APOTHECARIES,

(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS,

will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT

embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick-room and nursery.

*** GENUINE COD-LIVER OIL,

of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

DISPENSING OF MEDICINE.

G. OLDHAM AND CO.,

PHARMACEUTICAL CHEMISTS, AND APOTHECARIES,

From BEWLEY and EVANS',

No. 107, GRAFTON-STREET, DUBLIN,

(Corner of Suffolk-street),

BEG to return their grateful acknowledgments to the Medical Profession for the support they have hitherto received, and which they will regard as a fresh motive for exertion. Abstaining altogether from visiting as Apothecaries, except for the application of Leeches, Cupping, and such operations as are performed under medical advice, they will continue to devote themselves exclusively to the duties devolving on the pure Pharmacien.

Having had much experience in Practical Pharmacy, and being resolved to spare neither trouble nor expense in order to have every article of superior quality, they hope by attention, "carefulness," punctuality, and moderation of charges, to commend themselves to the approbation of those who may entrust them with their commands.

☞ *G. O. and Co. invite attention to their present stock of Surgical Instruments, all of which are manufactured on the most modern and improved principles.*

ON CATARACT OR OPACITIES OF THE CRYSTALLINE LENS.

By Arthur Jacob, M.D., F.R.C.S.,
Professor of Anatomy and Physiology in the Royal College of Surgeons in Ireland, and Surgeon to the City of Dublin Hospital.

(Continued from p. 53.)

THE SO-CALLED SYNCHISIS ETINCELANT.

In a former communication I alluded to a very remarkable and peculiar alteration of the lens which, from its rarity, as well as from its value as an example of extreme degeneration of organized animal structure, is well worthy of consideration; and especially so, because its nature has been mistaken by persons on the continent who have undertaken to describe it in ignorance of the accounts published in this country respecting its true character. This peculiar alteration or degeneration I described at a meeting of the Surgical Society on the 14th of January, 1843, in the following terms:—

"Dr. Jacob called the attention of the society to an appearance which presented itself in the eye of a person upon whom he lately operated for cataract in the City of Dublin Hospital. The man, aged 33, was, he said, what is called amaurotic, or in other words, his vision was very defective even in the other eye which was free from cataract, and therefore he was unwilling to operate from a conviction that he had an unsound retina to deal with; but at the earnest solicitation of the patient, he consented to let him have the chance which the experiment afforded. The cataract was lenticular, and although more of an amber tint than is usual at this time of life, was otherwise not uncommon. The lens was freely broken up with the needle through the cornea, and was easily separated into pulp and fragments, some of which fell into the anterior chamber, and no inflammation requiring attention followed. In a month the greater part was absorbed, and in six weeks the whole, leaving a shred of opaque capsule attached to the margin of the pupil, but not large enough to interrupt the passage of light. As the cataract, however, disappeared, the iris became studded with delicate brilliant scales of metallic lustre, so numerous and large as to be easily visible with the naked eye, and still more conspicuous with the assistance of a lens. They were irregular in form, but with surfaces so plane and polished that they reflected the light freely, resembling, in a remarkable manner, the particles of mica in granite. The appearance continued until the man was discharged, having been visible for about a month, and may probably continue so for some time. Sight, as had been predicted, was not restored, the retina being unsound. Dr. Jacob reminded the society that earthy, and perhaps crystalline deposits in the lens and its capsule were not very uncommon, and that they had been met of so dense a nature as to lead to the application of the term ossification to them, although not to be considered at all of the nature of real bone. They are probably phosphate of lime, or perhaps ammonio-phosphate of magnesia with phosphate of lime, but that he left to the chemists to determine. He said that on another occasion, in breaking up a cataract of somewhat the same appearance, he was surprised to see a quantity of what appeared to be delicate needle-shaped crystals diffused among the fragments, but these disappeared with the cataract as it was dissolved. He also exhibited a drawing of a capsular cataract, the consequence of injury, which he had removed successfully, and which had presented on the surface an appearance of such metallic lustre that he was obliged to make the artist represent it with silver leaf, and added that these brilliant cataracts, in a less marked form, were not very uncommon, but in all of them the disease was of long standing. Earthy deposits, he observed, were frequently found in the body of the lens in horses blind from cataract consequent on inflammation. The shell of bone sometimes found within the choroid of disorganized eyes, and generally called ossified retina, he observed, was probably of the same nature as these lenticular deposits."

I again called the attention of the society to the same subject on the 23rd of November, 1844, as follows:—

"Dr. Jacob said he had some observations to make on a peculiar appearance occurring in a cataract under his care at the City of Dublin Hospital. It occurred in a boy on whom he had operated about five weeks since. He had received a blow on the eye some years before which had cut the cornea and injured the iris, the black membrane of the aqueous humour on the back of the iris being torn from it and dragged in front. This led to cataract, with irregular pupil; it was evidently an unsound eye, and was one of those cases to which he gave the chance of an operation without any sanguine hopes as to the result.

He had broken up the lens, which was soft and pulpy, and thrown the fragments into the anterior chamber in the usual manner. In about a week a large portion of the pulpy matter had been dissolved, but mixed up with the remainder were a number of small brilliant scales, resembling particles of gold leaf, perhaps not of so metallic a lustre, but having more the appearance of mica. He called the attention of the students to them at the time, and though they had since then partially disappeared, they were now, in the fifth week since the operation, distinctly visible, moving about in the anterior chamber. They are now fast dissolving, and in a week or ten days will probably have altogether disappeared. He would not offer any conjecture as to the nature of these scales, if he had not recollected a case which had formerly come under his notice. It was an instance of cataract, produced, as well as he recollected, by injury also. On breaking up the lens, he was surprised to perceive it fall into a pulp in the anterior chamber, having the appearance of oil altered by cold. Some days afterwards on examining it with a lens of 2½ inch focus, a number of needle-shaped crystals or spiculæ appeared moving about in the anterior chamber, each about a line in length. Knowing that the crystalline lens was composed of delicate fibres, he at first imagined that these might be some fragments of it, but all doubts on that point were removed when he discovered that after some days they were not dissolved, but remained even more distinctly visible as needle-form crystals than before, and he was led to consider whether they might not have been crystals of some of the phosphates of lime of the same nature as the metallic scales he had been just describing. He thought it very probable that these were crystals of some phosphate of lime, as chemists, in speaking of that substance, described both crystalline needles and crystalline laminæ. Some persons might allege that these were merely fibres of the crystalline lens, but his objection to that was, that being so, they would have dissolved in a few days, while both the scales and needles to which he had alluded continued undissolved in the chamber for many weeks. It might also be objected, that in natural or healthy animal structure no crystalline deposits took place, unless the enamel of the teeth and porcelanous shells might be adduced as instances of such; but whatever objections might be urged against such an occurrence in health, he would say that they were applicable to diseased conditions of the body. [Dr. Jacob here exhibited a drawing of another cataract upon which he had operated in 1839, the surface of which presented a brilliant metallic lustre, and the texture of which, it being capsular and free from injury, was remarkably tough and firm.] This he considered somewhat of the same character, but not so crystalline or calcareous. He was not aware that these appearances had been described already, but he should not be surprised if it was so; for his engagements did not permit him to search for such a fact in the immense mass of medical matter delivered by the press to the profession in the last few years; it would be like seeking for a needle in a bundle of straw. Other parts of the eye were subject to calcareous deposits, even the cornea had been found with gritty particles in it, and those osseous cups, generally described as ossifications of the retina, were not uncommon. Calcareous deposits in the body of the lens had been described by Mr. Wardrop and others, and such were frequently found in the eyes of horses blind from cataract for many years. Conversion of the capsule of the lens into a material resembling egg-shell was not very rare; all showing that there was no difficulty in admitting that phosphate of lime, or some similar deposit, was often made in the structures of the eye."

Notwithstanding these circumstantial descriptions of this very curious form of disorganization, recorded in the 212th number of the Dublin Medical Press for January 25, 1843, and again in the 310th number for December 11, 1844, I find that it has been described and commented on in the continental journals without the slightest reference to my notices. In the *Annales d'Oculistique*, an ophthalmological journal, published in Brussels by Dr. Cunier of that city, a communication appeared in the number for November, 1845 (nearly two years after my first notice), from Dr. Desmarres of Paris, describing an example of the same disease. It occurred in a woman, aged 58, whose sight began to fail from cataracts about eighteen years before, and who had the operation of depression performed on her left eye seven years, and on the right three years, before Dr. Desmarres saw her; she then (September 22, 1845,) had dense capsular cataracts, dilated pupils, and tremulous iris, with little sight. These capsular cataracts were removed with a pair of nippers through an opening made in the sclerotic, and good vision followed, but in about a fortnight or three weeks after the following appearances were observed in the left eye: "Looking through the pupil, which was widely dilated, to the bottom of the eye, which was perfectly black, I saw (says Dr. Desmarres) scales attached, brilliant as diamonds, moveable, and of a size to be compared only to grains of sand. They occupied different planes in the posterior chamber, appearing generally twenty or thirty at a time; becoming displaced from below upward with the motions of the eye, and being replaced by others equally brilliant and numerous. All these little luminous moveable points reflecting the light with a vivid brilliancy, appeared to descend by degrees to the lower part of the eye, when it remained immoveable, and showing themselves in greater number as the motions of the eye were more extensive and sudden. There was no unusual appearance in the anterior chamber, and vision was as good as could be desired after an operation for cataract; the patient complaining of some *muscæ volitantes* only.

In the same *Annales d'Oculistique* for April, 1846, Dr. Sichel of Paris called attention to this subject, and relates a case of the same kind which had occurred to him in 1841. The patient, a boy, aged 13, suffered from hydrophthalmia of both eyes, the left being much larger than the right, but still so free from disease as to enable the boy to read. In the right, which was soft to the touch, and scarcely sensible to light, was a yellow capsular cataract adhering to the pupil. On tearing this capsule with the needle, a flow of turbid, yellowish liquid took place, mingled with a quantity of scales of a golden-yellow lustre, which fell into the anterior chamber and filled it up completely. When this subsided a second flow of semitransparent yellowish material followed, resembling boiling water in its motion. These appearances continued for several weeks, and some of the brilliant scales were visible even in 1844, three years after. Dr. Sichel adds significantly: "It is astonishing that Dr. Desmarres, who, in 1841 and 1842, being my clinical clerk, had seen with me this patient, should have lost all recollection of a fact so difficult to forget, and which gave peculiar interest to that which he himself published." But it appears that neither I, Dr. Sichel, nor Dr. Desmarres first noticed this curious disease, for it appears that M. Parfait-Landrau, an oculist at Perigueux, described it in a communication published in the *Revue Médicale*, t. iv., p. 203, in 1828. The patient was a gentleman, aged 70, who, for several years, had defective vision with *muscæ volitantes*. He says: "On looking into the depth of the posterior chamber, I could perceive little bodies oscillating in the bottom, shining with phosphorescent brilliancy. Notwithstanding the attention I had paid in this examination, seeing the novelty of the phenomenon before me, which ap-

peared of high interest to science, I distrusted my own judgment, and fearing that what I saw was the reflection of some external object, I dilated the pupil with belladonna, when M. Galy, of the hospital of Perigueux, also saw distinctly little bodies like fine powder of liquorice, and amongst the number, which was very considerable, were seen some having the brilliancy of filings of gold. These little bodies oscillated throughout the entire extent of the posterior chamber, and when the eye was at rest fell to the bottom, but on the slightest motion rose and again fell. All this took place at such a distance that no doubt exists that they moved about in the vitreous humour. They were so numerous that they were well seen with the naked eye, nevertheless we examined them with a lens. Four days after this, the eye was submitted to a second examination, in presence of Dr. Vidal, a member of the medical jury of the department, and first physician to the hospital, M. Galy, surgeon of the same institution, and M. Renaud, another surgeon: these gentlemen recognized the phenomena above described, and consider it a duty they owe to the interests of science to testify as to the correctness of the statements." M. Parfait-Landrau goes on to argue that these appearances serve to account for the *muscæ volitantes* and luminous spectra which so often disturb vision, but on this it is not here necessary to dwell. After all this, it seems strange that Dr. Desmarres should, in a work of considerable size on Diseases of the Eye, published in 1847, say: "There is not in science, to my knowledge, any observation similar to this (made by him), not even that of M. Parfait-Landrau."*

The reader will perceive that while I described this curious form of disease as occurring in the lens, subsequent writers on the subject referred it to the vitreous humour, and have actually named it accordingly. When the vitreous humour is disorganized by inflammation, and the hyaloid membrane loses its cohesion, the eyeball becomes soft to the touch and the iris generally tremulous; this has been named *synchisis*, and this supposed variety of it has been dignified with the title of *synchisis étincelant*, or *synchisis scintillans*. That the lens is the seat of the disease I entertain no doubt whatever. In one case I saw the peculiar material burst out of the capsule as I opened it with the needle through the cornea, and in the others the scales and needle-shaped crystals were so thoroughly embedded in the substance of the broken up lens, and were so obviously let loose in the aqueous humour as these fragments dissolved, that I could not be deceived. The description of M. Parfait-Landrau, I admit, supports the other view, for he saw these oscillating bodies in an eye which, although defective, was not considered to suffer from cataract; but as there are forms of cataract in which the capsule of the lens is distended with fluid, this may have been one of them, and in that fluid it probably was that these bodies moved. In Dr. Desmarres' case, the particles appeared upon extracting opaque capsules, and had probably been discharged from the lens in the previous operation of depression. Moreover, it does not appear that Dr. Desmarres' patient had any *synchisis* at all, for he says, after describing the disorganized state of the iris and its adhesions to the capsule, "*toutes les autres membranes sont saines.*" And again, "*les yeux avaient leur consistance normale.*" In Dr. Sichel's case there was a capsular cataract, but there is no reason for assuming that there was not a disorganized lens within it when it was opened. In M. Parfait-Landrau's case there was no softening of the eye, and therefore no *synchisis:* in fact, there is no evidence that the disease was in the vitreous humour. As to the possibility of anything floating about in a sound vitreous humour, it cannot be admitted for a moment; this structure, although a soft and delicate one, is a solid, and in a solid such particles could not move. As to the complete fluidity of this humour, even in softened eyes, much remains to be ascertained by careful dissection. It is much more probable that decomposition of the crystalline lens would afford products such as these described, than that a structure of such tenuity as the vitreous humour could generate them. The lens of all the structures in the body contains the elements of animal organization in a state of the highest concentration, and liable as it is to become detached from its capsule, although still retained within it, presents a condition of parts in no other place to be observed. It is, indeed, when so detached, a lifeless material enclosed within living structure, where, although it does not act as a foreign body, it undergoes changes as peculiar as the extraordinary state in which it exists.

* Without wishing to detract from the merits of French surgeons, it is only justice to those of other countries to remind the reader that while an acquaintance with the French language is so general elsewhere, that of German and English is very limited in France. Hence the facility with which even trivial communications made by Frenchmen obtain currency in England and Ireland, while valuable information afforded by us remains inaccessible to them; or what is worse, the information is used without acknowledgment, so as to appear original. This, however, is not perhaps so great an evil as the wilful and obstinate ignorance, or something worse, ostentatiously displayed in other places, and from which some London writers are not entirely free.

OF THE CURE OF CATARACT.

I BELIEVE it may with safety be asserted, that opacity of the crystalline lens has never been removed; or in other words, that cataract when once formed has never been cured. Defects of vision attributed to opacity of the lens have, it is true, been improved by medical treatment, or have disappeared in time, but credible evidence of these effects having been caused by opacity or cataract is not forthcoming. It is also true that dishonest men have persuaded ignorant and credulous people that cataracts existed in their eyes, and that they had removed them by external applications, but this of course only explains the origin of the erroneous notion that cataract has sometimes been cured by medicinal agency. So little reliance is placed on internal or external remedies for the cure of cataract, that they are seldom resorted to, and it may therefore be said that a fair trial has not been made of them; but incipient cataract so often exists with incipient amaurosis, for which the most powerful remedies, such as bleeding, blistering, mercury, and iodine, are used, that ample opportunity of testing their influence has been afforded. Inflammation and amaurosis of one eye is also often actively treated while cataract exists in the other, yet the opacity is not removed, or any alteration made in it. I have myself repeatedly tried mercury, iodine, and blistering in incipient cataract caused by slow insidious inflammation of the eye, without success, and I have seen many cases in which they have been tried by others with the same result. I am, therefore, convinced that true cataract has never been cured by medical treatment. Spontaneous disappearance of cataract is spoken of, and every man has some case to record in which persons previously blind from cataracts have suddenly recovered sight, but I never yet have been able to ascertain to my satisfaction the real state of the eye previous to the alleged

change. An opaque lens sometimes, but I believe very rarely, is detached from its connexions enclosed in its capsule, and falls down below the place of the pupil in consequence of disorganization of the hyaloid membrane; but this cannot be correctly considered a spontaneous disappearance of opacity. It remains, therefore, only to come to the conclusion that sight lost by cataract can be restored by removal of the opaque lens from the axis of vision by operation only. There is, however, one form of blindness from opacity of the lens which is cured without artificial means, and that is cataract from wound or rupture of the capsule. As I have already said, it is fully established by daily experience that penetrating wounds of the eye by sharp-pointed substances, such as fragments of glass or earthenware, thorns or nails, or by awls, forks, or other instruments of that description, are immediately followed by cataract and blindness; and on closely examining such cases, it is found that the capsule is torn open and the lens exposed to the contact of the aqueous humour. It is also now fully established that in such cases the lens imbibes the aqueous humour, swells, softens, dissolves, and is absorbed, leaving the eye free from opacity, and as perfect for the purposes of vision as after the most successful operations. This may be called a spontaneous cure of cataract, but it is not a cure or removal of opacity of the lens; it is a total removal of the lens itself.

Three different methods are employed for the cure of cataract by operation. It is either removed altogether from the eye through an incision made in the cornea; forced down below the pupil into the vitreous humour; or broken into fragments, and left to be dissolved and absorbed. The first is, as every one knows, the operation of extraction; the second, that of depression, or couching; and the third, that of breaking up, or division. These three methods might, however, be reduced to two; for in result I am convinced that depression and division are the same, the lens in both cases being ultimately absorbed; but as the operations are different they must be separately described.

THE PATHOLOGY OF INFLAMMATION AND FEVER.

By H. Freke, A.B., M.B., M.R.I.A., Dublin.

In a series of papers which I am about to furnish for insertion in the Medical Press, my object shall be to inquire into the pathology of inflammation and fever, *strictly avoiding the introduction of anything having the character of mere hypothesis or theory.* I shall attempt to establish the two following propositions upon principles that admit of the *clearest demonstration*—namely:

1st. That during acute inflammatory action, there is not (as is I believe generally supposed) any augmentation whatever of the normal amount of fibrine contained within the *system generally;* that, on the contrary, the actual amount of fibrine contained within the general system is not necessarily affected in any way by the occurrence of inflammation; but that the *local* accumulation of fibrine—that is, the augmentation (on the occurrence of acute inflammation) of the amount of fibrine normally contained *within the vascular parietes* is the result of the normal extravasation of fibrine from the vascular system into the extravascular interstices having for the time been suspended. That is, the fibrine which normally would have been extravasated from the vascular system into the extravascular interstices (to be there appropriated to the purposes of nutrition) is, during the inflammatory process, retained *within* the vascular system, thereby causing an accumulation within the vascular parietes of that fibrine which, under normal circumstances, would have existed *extravascularly.*

2ndly. That the essential element in fever (whatever be its type) is a demand on the ganglionic centres of the nerves of the circulating system for a greater amount of nervous influence than those ganglia are adapted for generating in a given period of time. In other words, an inadaptation on the part of those ganglionic centres to generate in a given period of time an amount of nervous influence proportional to the amount of stimulus communicated to the peripheral extremities of the ganglionic nerves. That the direct effect of this is *(for the most part*)* a suspension generally throughout the system of the normal extravasation of liquor sanguinis from the vascular system into the extravascular interstices, and consequently (as a remote effect) a corresponding suspension generally throughout the system of the normal process of assimilation or nutrition.

In order to render my observations upon these two propositions as simple as possible, and to disembarrass my readers of the difficulty of bearing a number of deductions in the mind without being able to recognize their immediate application, I shall briefly lay down in anticipation the line of inquiry I intend to pursue. I shall divide my inquiries into two parts. The first shall be devoted to the consideration of the formation and appropriation of fibrine in relation to the ordinary process of nutrition. In reference to this subject, I shall attempt to show that fibrine is generated and deposited *within* the vascular parietes, and that its appropriation to the purposes of nutrition takes place *extravascularly.* In the second division of my subject, I shall inquire into the nature of the mechanism of the *human* circulatory apparatus—that is, into the nature of the provision which has been made by nature for propagating the blood in strict accordance with the requirements of the human organism. In relation to this inquiry, I shall attempt to establish the following propositions—namely: 1st. That in the human organism, there are two distinct divisions (if I may so term it) of the sanguineous circulatory apparatus which have been so constructed as to enable them to contract (according as may be required) *with various degrees of activity or energy.* The one may be termed the cardiac division, including the arterial system; the other, the capillary division, comprising the capillary system generally throughout the organism. That the parietes of these two divisions of the circulatory apparatus require the operation of a *stimulus* to cause them to contract; and that the stimulus provided by nature for that purpose is the nervous influence generated in the ganglionic centres of the nerves of the circulatory apparatus. That this nervous influence itself must be subject to control, and must operate with various degrees of activity or energy at different times, and consequently must have been provided by nature with a stimulus which can regulate the degree and time of its action. That the stimulus which calls into operation the nervous influence generated in the ganglionic centres of the nerves of the circulatory apparatus is consequently the *primary or remote* cause of the contractions of the parietes of the sanguineous circulatory apparatus; the nervous influence thereby called into action being the *immediate or proximate* cause of those contractions. 2ndly. That the seat (that is the locus of the application) of the stimulus which is the *primary or remote* cause of the contractions of the parietes of the *two divisions* of the circulatory apparatus is the latter or *capillary division;* and that the stimulus communicated, in the capillaries, to the peripheral extremities of the ganglionic nerves of the circulatory apparatus, causes a corresponding or proportional amount of the nervous influence which is generated in the ganglionic centres of those nerves to be propagated in a *divided direction*—namely, one portion thereof to be transmitted in the direction of the appli-

* My motive for the introduction of the words "for the most part" into the above definition of fever will become apparent when we engage in the consideration of the subject of fever in detail.

cation of that stimulus that is towards the capillaries, and the other in the direction of the centre of the arterial system or towards the heart. That consequently the seat (or locus of the application) of the *primary or remote cause* of the cardiac contractions is *the general capillary system.* And 3rdly. That the nervous influence (as already observed) which (on the application of the *primary or remote cause* of the parietal contractions) is propagated in the divided direction referred to; that this nervous influence is the *immediate or proximate* cause of the contractions of the heart and of the capillaries. In the development of these two divisions of my subject, I trust I may be able to demonstrate to the satisfaction of my readers the two foregoing propositions on inflammation and fever.

(To be continued.)

Paris, July 28, 1851.

CASE SIMULATING HIP-DISEASE.

By Edmund Sharkey, M.B., T.C.D.

I have found the following case among my notes; and as it caused much anxiety to the friends and some embarrassment to the medical attendants at the time, and though not of common, is yet of occasional occurrence, it has appeared to me to possess a practical interest:—

Jersey, December 11, 1845.—A young gentleman, aged 13, while walking in the street, five weeks ago, was suddenly attacked by pain of his spine, so severe as to cause him to stagger. By his family it was considered as rheumatism. Sudorifics were administered, by which the pain was removed from his spine, but fixed in his hip, where it has since continued with very little variation, though treated by anodyne frictions, blistering, warm baths, Dover's powder, quinine, turpentine in small doses, and carbonate of iron; of which the turpentine alone seemed for a time to be beneficial.

Present state.—In attempting to walk, his knee is flexed, and he steps on his toes, and limps very much. On measuring, there is no difference of length between the two thighs, nor is any fulness to be detected on the affected side. On pressing, however, the head of the femur against the acetabulum, or flexing the thigh on the pelvis, considerable pain is complained of, and chiefly referred to the upper rim of acetabulum, at a point tender to the touch. No pain is felt in any other part of the limb; the general health is unaffected. I ordered warm baths, frictions with tartar emetic ointment, and the following powder three times a day:—

℞ Hyd. c. creta, gr. iij.
Quinæ sulph., gr. ¼.

29th. A small amount of relief has been experienced; evening exacerbations, which were before complained of, having ceased. But little irritation has been produced by the unguent. ant. tart. Ordered, quinæ sulph. in solution, and shower baths.

January 13, 1846. On examination to-day, there appeared to be a slight fulness over the crista ilii, which is painful, and very tender on pressure. A good many pustules, with surrounding inflammation, have appeared, having been produced by fomentations with warm vinegar and onion juice. He has been for some days taking calomel, gr. i., opii, gr. ½, twice a day. Leeches also were applied.

30th. In consequence of increase of tenderness, leeches were repeated, also warm baths, and he was ordered ten drops of Lugol's solution of iodine in decoct. sarzæ, three times a day. He has also had some hot air baths, which produced considerable perspiration, and were followed by general tranquillity; but did not remove the tenderness nor apparent fulness of the part, in which the superficial veins are much developed.

February 5th. His mouth being slightly touched by the mercury, the pills were omitted. To continue the iodine with decoct. sarzæ; to apply cataplasms.

9th. In consultation with Dr. Leigh, the spine was examined by percussion, but no tenderness detected. This, however, is very great on pressing crest of ilium and under os ischii; also on percussing the trochanter. Measurement detects no difference in length. The probability, therefore, is against hip-disease or lumbar abscess, and in favour of its being a muscular affection, perhaps caused by a fall three months ago. We resolved on applying a mercurial plaster over the painful part; and with a view of overcoming the muscles and drawing the head of the bone out of the joint and fixing it, weights with pulleys were applied, which kept up a constant traction. To take—

Hydr. c. creta, gr. iij.
Pulv. Dov., gr. iiss.
Quinæ sulph., gr. ½, ter in die.

18th. Has been since free from pain while at rest; he thinks that pain even on motion is less. Spirits and appetite continue unimpaired.

27th. Since last report has been using the following liniment:—

℞ Ung. hydrarg. fort., ʒi.
Iodinii, gr. x.
Tr. opii, ʒi.

Also warm bath, with douche on affected part.

He was permitted to leave his bed and take off the weight during the day. The pain has returned to the part, and has extended to some distance round crista ilii.

March 5th. Acupuncturation was now tried, three needles having been introduced about half an inch behind crest of the ilium, and left in for six hours. To take—

Tinct. fer. mur.
Tr. iodinii c. āā. gtt. xv., in decoct. sarzæ.

7th. Three needles again introduced, nearer to crest of ilium than the last; left in six hours.

11th. Is rather worse.

14th. Cupped and scarified (to about eight ounces) behind seat of pain. Dressed with ung. ant. tart.

16th. Has suffered much more since operation.

23rd. Anthelmintic medicines were now given, with a vague hope that it might be connected with the existence of worms: none, however, appeared.

April 6th. About a week ago he was removed to the seaside, and enjoyed an immunity from pain till yesterday, when it returned. General health improved; he has not the pain without intermission; it sometimes suddenly leaves him, sometimes remaining until he falls asleep, and then ceasing. He continued to improve slowly till—

June 14th, when I have the following note:—"Has lately taken some *very hot* baths, having found great relief from one accidentally given of a higher temperature than usual. The result is, that he has become *perfectly well;* he describes 'something as having *given way,*' in the situation of the pain, while immersed in one of them." I should have mentioned that he is said to have had a similar attack some years ago, which, after having resisted treatment, disappeared of its own accord quite suddenly—a circumstance which suggests the notion, that in the last attack perhaps a similar result might have followed; and, moreover, perhaps that it may have been retarded by the "nimia deligentia medici." He went subsequently into the navy, and was, I understand, similarly attacked while in the Mediterranean, and invalided in consequence. This last attack yielded to the hot air bath administered by means of the bed-lamp. He has rejoined his ship, and has become a hale young man.

There can be little doubt, I think, that the affection is to be placed among the neuralgiæ, and that it had, from first to last, nothing inflammatory in it. The fulness at one time observed about the hip-joint was probably analogous to the infiltration of the cellular tissue sometimes seen in cases of hysterical neuralgia; and, like it, quite independent of vascular action in the commonly received acceptation of the word, though probably approximating closely to the pathological condition lately described under the name of "Angioleucitis."

Ballinasloe, July 31, 1851.

CASES OF POPLITEAL ANEURISM TREATED BY COMPRESSION.

(Under the care of Mr. WARD in the London Hospital.)

A HEALTHY-LOOKING and temperate Irishman, aged 45, a lighterman by occupation, came under Mr. Ward's care, on the 6th of May, 1851, with the right popliteal space occupied by a well-defined, strongly-pulsating tumour. The latter was about the size of a small orange, and rendered the posterior boundary of the space convex and prominent, and it likewise caused the integument to protrude internally and externally. In the latter direction, it formed a convexity in front of the tendon of the biceps muscle, which was more marked than in the former. The extent of the tumour was easily defined by the fingers, its surface was smooth, and the sac gave to the touch no evidence of being otherwise than of uniform density. It expanded with each impulse of the femoral artery, and a loud *bruit de scie* was heard with each dilatation.

During the state of distension of the tumour, the right limb measured round the knee, immediately above the upper part of the circumference of the patella, fourteen inches and five-eighths; during its contraction, when the current of blood had been stopped by pressure made on the femoral artery in the groin, the measurement was fourteen inches and a half. The surface of the limb was warmer to the touch than the left, particularly in the neighbourhood of the knee-joint, a little below it. The right leg was somewhat swollen, and measured round the calf fourteen inches and a half; the left gave twelve inches and a half. The posterior tibial artery of the affected limb pulsated less strongly than that of the left. The anterior tibial arteries could not be felt beating over the ankle-joint, from their being in all probability more than usually overlapped by the extensor proprius pollicis. The anterior malleolar branch of the fibular artery, in both limbs, was more than usually developed, and pulsated very distinctly; the right more than the left. Several small superficial veins were observed in a state of distension around the inner part of the knee-joint, and the upper and inner part of the leg. Similar vessels were not remarked in the other limb. The pulse was 60, and regular; the heart's sounds and action normal.

The patient stated that about three weeks prior to admission, "he knelt down for about a quarter of an hour to clean about deck, and found that he could not get up without difficulty, and had a job in straightening his knee." On getting up he detected a small swelling in the ham, which was free from pain for about a week; pulsation in it did not attract his attention. He continued at work on board a lighter for three weeks after the above-mentioned circumstance, continuing to move heavy weights; and for two or three days before Mr. Ward saw him, the patient had been more than usually occupied. His leg had now commenced swelling, and appeared red, and it was on this account that he consulted Mr. John Hewitt, the tumour itself not appearing to have given the patient much anxiety. Mr. Hewitt detecting the nature of the case, at once sent the man to Mr. Ward.

The patient was placed on the middle diet of the hospital, which consists of four ounces of meat with potatoes, five days in the week; on the other two days, of vegetables and soup. The patient was requested to take as little fluid as possible, and the beer usually allowed was omitted. He was kept perfectly quiet in bed for nine days, during which time an occasional aperient was given.

A femoral truss was then applied to the artery on the groin, the pad of the truss being connected to the extremity of the bow by a screw, which could increase or diminish the pressure exerted on the vessel. It acted, however, but imperfectly, and it was laid aside for another, which fulfilled the indications no better. The result, however, of the slight pressure which had been exerted by the two instruments during a fortnight, was an evident diminution in the size, impulse, and throbbing sensation of the aneurism.

Dr. Carte's new instrument (a full description of which will be found in Mr. Tufnell's recent work on the treatment of Aneurism by Compression) was now had recourse to. The night prior to its application, the groin was carefully shaved, and dusted over with French chalk, and the apparatus was applied on June 3rd, according to the directions given by Mr. Tufnell.

The patient was ordered a scruple of acetate of potash three times a day, and half a drachm of compound jalap powder every other morning. The mattress on which he was placed was firmly fixed to the bed frame, the sheets and pillows being also attached by means of bandages. Prior to the pad of the instrument being applied to the groin, the leg was slightly flexed on the thigh, and the latter on the pelvis; the entire limb was then somewhat everted, and made to rest on the outer part of the knee-joint, upon a square well-stuffed pad, which was fixed so as not to slip. At the bottom of the bed a large pillow was secured by bandages, and served as a "*point d'appui*" for the feet, so that by this means the man was unable to glide; and a large cradle was placed over the body, in order to prevent the bedclothes interfering with the proper action of the instrument.

For twelve consecutive days—viz., from the 3rd to the 15th of June—Dr. Carte's instrument was made use of, and the femoral artery compressed on the pubis; the pressure, however, being never so great at any time as to stop the impulse in the tumour, and being entirely remitted when pain was complained of.

Mr. Ward expressed the belief that with the aid of a circular thigh-compressor, Dr. Carte's instrument would have brought about a cure; but from the circumstance that the pelvic apparatus slipped somewhat, and that the perpendicular side-rod of the instrument was rather too long, and not firmly grasped at certain parts by the pinching screw, the pad could be adjusted but for a short time, and was ever slipping. The apparatus was consequently laid aside for the requisite alterations. During its application, however, evident progress had been made; for on the sixth day after it had been used, the patient felt a burning sensation all down the thigh, leg, and knee. The impulse of the tumour had sensibly lessened, and it felt harder and denser to the touch. These satisfactory symptoms continued till the day on which the instrument was laid aside, on the night preceding which, the man had moreover experienced a peculiar sensation along the lower and anterior part of the thigh, as if something hot had been thrown over him, and likewise a crampy feeling in the tumour.

In the afternoon of June 15, being twelve days after the first application of the instrument, a pressure of a six-pound weight (an ordinary meat weight with a ring at the top) was applied to the femoral artery over the pubis. The skin over the vessel, which had become very red and tender to the touch, was carefully dusted over with French chalk, and covered with a piece of lint, and a box-wood pad. The patient bore this weight without much inconvenience, and, with a gentle application of the hand, the weight was quite sufficient to check the sensible impulse in the aneurism. It was kept on the groin for an hour and a half, at the end of which time a circular thigh-compressor, furnished by Bigg and Co. of St. Thomas's-street, Borough, was applied to the upper third of the thigh.

The use of the weight at the groin, and the instrument, were now alternately had recourse to, a four-pound weight, however, now and then, being substituted for the use of the six, and applied at the same time as the aneurism compressor, which latter was then so arranged as to exert but a moderate amount of pressure compared with that employed when acting by itself.

The patient, having been induced to take a personal interest in the principle and practice of the treatment, regulated the pressure himself without any difficulty. The circular compression was employed more than the weight, but neither the one instrument nor the other was kept applied more than an hour and a quarter, at the most.

At night time, when the patient felt inclined for sleep,

the compressor was in the first instance had recourse to, and when the application of the pad of this instrument caused uneasiness, and he happened to be dozing, he woke up and adjusted the weight to the groin, and then relaxed the compressor.

This line of treatment was kept up without intermission for five days; the aneurism became consolidated on the third day after its application, pulsation stopped, and the bruit was no longer audible. During this interval the following symptoms were observed:—

June 16th (first day).—The tumour is less in size, and much more solid, but very tender on pressure: a small artery can be felt pulsating over the inner condyle of the femur. Temperature at the right knee, 87 deg.; at the left, 86 deg.

17th (second day).—At twelve o'clock last night, a cutting pain in the shin-bone, lasting about two minutes; at two in the morning, a sudden burning heat along the anterior and outer part of the thigh.

18th (third day).—Slept but little last night; pain in the shin came on, and lasted about an hour; at five in the morning felt a cramp about the knee, and six hours afterwards the patient says that all pulsation ceased. None can be detected in the tumour or in the posterior tibial artery. Two superficial vessels are detected pulsating at the inner side of the knee: the one two inches, and the other two inches and a half, from the side of the patella.

On the first day after the tumour had ceased to pulsate, another small vessel could be felt pulsating on the outer side of the knee-joint, one inch in front of the biceps tendon.

On the second day, a small artery could be felt feebly beating over the centre of the tumour, with about half the force of those by the side of the knee; and on the seventh day the patient had the sensation of a needle darting through the back of the thigh one or two inches above the tumour; this occurred three or four times.

Nine days after the pulsation in the tumour had ceased, the patient was permitted to get up from bed for a few hours, and on the day following he kept up for five hours. During this time he walked at intervals on crutches, the leg bent at an obtuse angle with the thigh and the limb supported by a bandage passed round the neck and sole of the foot.

From this time the man made rapid progress, the bandage was laid aside in a few days, and he walked without difficulty, but slowly, in about a fortnight. The foot and leg became a little swollen towards night, though the œdema regularly subsided in the morning.

The patient left the hospital on July 19th, about one month after the application of the weights and Bigg's compressor; the tumour in the ham being not larger than a lime, and so firm, that a gentleman, who was unacquainted with the history and progress of the case, said that it gave him the idea of being a fibro-cartilaginous exostosis from the back of the femur.

The pulsation in the posterior tibial artery had returned, but was very feeble; the femoral could be traced beating as far as Hunter's canal. The patient was directed to remain quiet for a week, and then to resume his duties with caution.—*Lancet.*

New Method of treating Tubercular Ulceration of the Testicle.—An essay was lately read at the Academy of Medicine, Paris, by M. Malgaigne, in which he described the forms of fungus of the testicle which constitute the variety of disease to which he referred, and related the various modes of treatment adopted by surgeons, concluding by proposing to raise both the integuments and the morbid structures at the same time, penetrating even to the tissue of the testicle, and then attempting to produce union by the first intention. This plan, the author urged, had the advantage over castration that it afforded an opportunity for a portion of the organ to resume its functions at some future time, if any healthy structure at all remained; and if no healthy gland exist, he added, the patient is no worse off, and has not the melancholy knowledge that he has been castrated.

A CASE OF SPASM OF THE ŒSOPHAGUS AND AIR-PASSAGES FROM DORSO-INTERCOSTAL NEURALGIA—THE SPASM OF THE FORMER SIMULATING ORGANIC STRICTURE.

By D. J. Cain, M.D.,
Physician to the Marine Hospital, Charleston.

About the middle of October, 1849, Tissey, the property of Mr. W. B—— of this city, aged 32, of a highly hysterical constitution, and subject to dysmenorrhœa and asthma, both spasmodic and catarrhal, began to experience some difficulty of deglutition when either solids or fluids were taken. Supposing that the dysphagia was caused by soreness from cold, she paid very little attention to it; but as it continued to increase, her fears were, at the end of two weeks, greatly excited as to her situation, and I was called to see her. She referred the obstruction to a point about four or five inches below the glottis, say behind the top of the sternum. It was at this spot that solid or fluid aliment, when attempted to be swallowed, would be momentarily arrested in its passage downward, and would cause considerable soreness, and sometimes acute pain. She complained of no uneasiness elsewhere; her digestive organs were in a healthy state; there was no fever; in short, no malaise.

As this case, in its inception and progress thus far, bore a strong resemblance to cases of organic stricture generally, and particularly to one observed by me in 1848, and recorded in the March issue of this journal for that year, which terminated fatally, I concluded that it was of that nature, and was apprehensive that it would be equally unfortunate in its result.

Without delay, I introduced the probang, with the sponge attached, into the œsophagus, in order to ascertain, if possible, the degree of the constriction. When it reached the spot mentioned above, it excited so much irritation that there was a strong contraction of the canal; but by firm pressure continued for a few seconds, the spasmodic contraction was overcome, and the sponge passed beyond. She was directed to frequently take a piece of alum in her mouth, and to swallow it when dissolved; also, to use a strong rubefacient liniment upon the throat and upper part of the chest; the diet to consist of semi-fluid substances, such as arrow-root and milk, rice or hominy, gruel, &c.

At the expiration of a week, there was a decided improvement in her condition. She swallowed with much greater ease, and there was much less soreness. She went into the country with her owner on the first of December, 1850, and continued to improve until the morning of the 17th day of the month, when, after protracted exposure the preceding day to bleak, cold weather, getting the feet wet, &c., she had a sudden return of the difficulty of swallowing, but this time it was accompanied by a considerable degree of dyspnœa. On the approach of night, all the symptoms were aggravated; high febrile excitement supervened; the dyspnœa increased, until it amounted to orthopnœa; a sense of constriction and spasm of the chest in the region above spoken of was superadded to the other symptoms, and suffocation appeared to be imminent. At about eight p.m., her situation having become in the highest degree alarming, her owner despatched a messenger for Dr. Moultrie, who resides a few miles distant.

To inquiries addressed to him, in reference to the symptoms and treatment, as well as his opinion of the cause of the attack, Dr. Moultrie kindly made me the following reply:—

"On the 13th of December, I visited the case for the first time, about midnight, immediately after a severe paroxysm of spasmodic constriction, several of which I was informed had occurred before my arrival, at intervals varying from half an hour to an hour. They seemed to recur independently of any casual exciting cause, or act of deglutition, and were distinctly paroxysmal, although if any material was attempted to be swallowed, some time after a paroxysm, it appeared to occupy to the succeeding one the relation of an exciting cause. The suffering was intense, and upon the first

blush of the case, presented immediate and pressing claim for relief, while time could be allowed to inquire into the nature and pathology of the case. From representations made to me by Mr. and Mrs. B——, my mind had been preoccupied with the idea of organic disease, still the manifestation of disturbance in the functions of the nerves distributed to these organs, constituted the most prominent source of the morbid phenomena at the time. I did not so distinctly, as you have done, locate the irritation in the dorso-intercostal nerves, but was induced from the history, non-medical at the time, to regard the case as having commenced with catarrh, sore throat, and probably some degree of œsophagitis; the latter condition being most persistent, and by its continued existence occasioning eccentric nervous irritation, which was reflected and manifested by spasm of the œsophagus, and the other morbid signs. I find I am indulging farther in speculation than you may desire, and will now confine myself to the treatment of the case.

There being present some slight febrile irritation, and nothing contra-indicating it, a few ounces of blood were abstracted, and a moderate dose of oil administered immediately after a paroxysm, which was swallowed without any difficulty; a mustard pediluvium was ordered, and fomentations over the chest and epigastrium. Relief soon appeared to follow these measures. The succeeding paroxysms began to moderate, and anodynes, to which I had looked as the chief resource to arrest the recurrence of the attacks, were administered. Morphine was given *pro re nata*. Instructions were given to repeat the doses, as occasion called for them. Begging your indulgence for the brevity of this report, I am, dear sir, respectfully yours, W. L. Moultrie."

The night after this attack, being on a visit to the family, I saw her in the situation described by Dr. Moultrie, scarcely any amelioration in the symptoms having taken place. The spasms of the larynx, trachea, and œsophagus were terribly severe, frequently causing her to scream out. They were intermittent, recurring about every fifteen or twenty minutes, and lasting from three to five. I thought several times, while I was seated at her bedside, that she would die from suffocation, as it appeared to me that the constriction of the air-passages was so great, the air penetrated with great difficulty and in small quantity. She still had high fever, and complained of chilliness of the whole body, but more particularly of the feet and spine. I watched with great interest her attempts at swallowing drink (for solids were out of the question); she could not take more than a dessertspoonful at a time, and it was invariably arrested for the space of from half a minute to a minute at the constricted part, then, with a gurgling noise, it passed down.

As I had, on several occasions previously treated her for dorso-intercostal neuralgia (spinal irritation), I suspected that an irritated state of the motor nerves of those organs, proceeding from the spinal marrow, might have some agency in the causation of the spasm, if indeed it was not the sole cause. On passing my finger down the spinous processes of the vertebræ, with the view of assuring myself on this point, I detected a very tender spot, extending from the sixth cervical to the fourth dorsal vertebræ, and the true nature of the disease was at once revealed. Sinapisms were applied to that part, hot bricks to the feet, and Dr. Moultrie's prescription given *pro re nata*.

The next morning she was somewhat relieved, and being compelled to return to the city, I did not see her again until the 4th of January, when she came back to the city with the family; but learned that Dr. Moultrie had continued his attendance until she was sufficiently relieved to dispense with it; that her improvement had been progressive, though slow, and that she was invariably affected by a damp change in the weather. She still complained of more or less soreness in swallowing, but there was no spasm. Convinced that the dorso-intercostal neuralgia was the sole cause of the morbid phenomena, I determined to use active counter-irritation to the tender part of the spinal column. A flying vesicatory was applied, and as it did not entirely relieve the tenderness, it was repeated twice, at intervals of ten days. After the last application it disappeared, and the soreness of the œsophagus, trachea, &c., with it. From this time until November, 1850 (a year from the date of the commencement of the disease), she enjoyed her usual share of health. About the 20th of that month she again begun to experience some dysphagia, &c. Having again detected the tenderness of the spine, I applied a blister, and the difficulty of deglutition was immediately relieved.

Remarks.—The progress and termination of the case prove that my original diagnosis was incorrect; that, instead of inflammation followed by permanent stricture of the walls of the œsophagus, one of the most formidable diseases that falls to the lot of the physician to treat, there existed an irritation and spasmodic contraction of that canal, from irritation of the intervertebral nerves, which soon extended to and involved the mucous and muscular (?) tissues lining the air-passages. Therapeutics sometimes materially aid the physician in making a correct diagnosis; in this instance, they were positively confirmatory of my last diagnosis.

Having elsewhere considered, at some length, the application of the views of Marshall Hall, on the physiology of the nervous system, to the explanation of various important morbid phenomena, I deem it unnecessary to go over the ground again in reference to the present subject. I have there shown, that according to this distinguished physiologist, there are two sources of irritation or other morbid action that may excite the same, or similar phenomena, in organs or parts removed from that which is the original seat of disease. These are *excentric* and *centric*. The irritation and subsequent inflammation of the stomach, caused by the state of gestation, is a familiar illustration of the mode of operation of the former of these sources. The gravid being, in a measure, a pathological state of the uterus, gives rise, through the medium of the spinal marrow, to irritation of the stomach, which, if continued, may eventuate in inflammation. Spiculæ of bone, &c., irritating the membranes of the brain or spinal cord, or those organs themselves, thereby causing spasm of some part, or of the whole muscular system, is an example of the *centric* source.

A French physician (M. Beau, I think) has conclusively established that dorso-intercostal neuralgia, from what cause soever, frequently excites excruciating pain in two points—viz., about the middle of the distance between the spinal column and the mesial line, and at the mesial line itself; for it is at those two points that the nerve gives off a filamentous expansion. These pains are so severe, of such a stabbing, lancinating character, as to cause them to be sometimes mistaken, by those who are not acquainted with the nature of the diseased action, for pleuritic, if the origin of the nerve distributed to the intercostal muscle is affected. When the nerve which supplies the stomach is affected, the pain resembles cramp, &c.

Now, although these pains occur in a great many different parts of the body, simulating various diseases, such as peritonitis, angina pectoris, spasm of the intestines from inflammation or obstruction, &c., besides in those already mentioned, yet I have seen the account of but one case at all resembling that which fell under my observation, and in this the larynx alone was affected, the other parts of the respiratory apparatus and the œsophagus not being involved. This case, which is reported by Dr. Vigla of Paris, in one of the French medical periodicals, was not considered by him as caused by the irritation of the dorso-intercostal nerves. It was somewhat akin to hydrophobia. The patient died on the fifth day from the commencement of the attack, asphyxiated by the spasmodic closure of the glottis. In my case, the disease would, in all probability, have terminated in the same way, and from the same cause, had she not experienced relief from the treatment instituted by Dr. Moultrie.

In respect to the treatment of the case, it is evident that the alum, as recommended by me in the early stage of the disease, could have been productive of no good effect, and that the improvement which took place, up to the time of the attack in the country, must have been due

to some other cause, such as a dry state of the weather, spontaneous subsidence of the irritation of the intervertebral nerves, &c. The plan of treatment pursued by Dr. Moultrie for the relief of the attack, was unquestionably admirably adapted to that end, but it was at best only palliative, in view of the recurrence of the disease, for neither he nor myself suspected, at that time, its true cause.

The counter-irritation employed by me, on discovering the nature of the cause, was followed by complete relief. Even this was, however, but temporary, as she had a recurrence of the disease after the lapse of about ten months.

The sagacious physician will readily perceive that the real source of the disease remains unreached. In order to effect a permanent cure, it will be necessary to go back and remove the first links in the chain of morbid action, consisting in the rheumatic and hysterical states of the system, on which the dorso-intercostal neuralgia depends. —*Charleston Med. Jour.*

ON PROGRESSIVE MUSCULAR ATROPHY.

By M. Aran.

Symptoms.—Several circumstances confer on this form of atrophy a special character. A debility is first observed in a single limb, or rather part of a limb, so as to confine it to the execution of certain movements, gradually, however, involving a larger portion of it, and generally extending to the opposite one after a time. Cold and fatigue augment it, while cramps and subsultus often accompany it. Emaciation of an irregular character follows this, affecting certain muscles only instead of the mass of the limb, and therefore giving rise to various deformities, and finishing with the destruction of the muscular structure and complete annihilation of function.

In nine out of the eleven cases it commenced in the *upper* extremity, the right side suffering first in seven, the left in two, and in two both being simultaneously affected. Sometimes the affection first appeared in the muscles of the shoulders or those of the upper part of the trunk, at others in the fleshy masses of the arm or forearm, but most commonly in those of the hand, or the little muscles of the thenar and hypothenar eminences, and the interosseous spaces. Side by side with the atrophied muscles others are found unaffected, even their congeners, which to some degree supply their places. Moreover, in the case of some of the larger muscles, easily separable into bundles of fibres, some of these may remain unaffected. The muscles of the upper extremity, which the author has hitherto always found exempted, are the triceps in the upper arm, and some of those of the anterior part of the forearm, and especially the pronator teres and flexor carpi radialis. Intelligent patients have observed the wasting almost simultaneously with the weakness of the part; and if we find a slight wasting of the thenar or hypothenar eminences, or a too-marked depression between the interosseous spaces, combined with weakness of the hand, and unexplained by any other cause, we may suspect the existence of this disease, our convictions gaining in certainty as more muscles become after a time involved. Normally, the muscles offer a certain amount of *resistance* and *elasticity* on pressure, and in all *other* atrophies, from whatever cause, these qualities, though *diminished*, are not *lost*. Here they are absent, for not only is the muscle reduced in volume, but its tissue is probably replaced by cellular-adipose tissue, giving to the touch a sense of extreme softness (varying, however, with the degree of the disease, and the propinquity to osseous tissue), while the will cannot impress the slightest tension upon it.

Fatty Transformation in all the cases is at present only highly probable, for its reality has as yet been shown in but one case, the only one in which an autopsy has taken place.

In an early stage of the disease obstinate cramps, and in a later one subsultus and *fibrillary contractions*, may be present. These last may consist of the isolated and involuntary contraction of certain of the muscular fibres, being sometimes so numerous and continuous that the muscle seems in motion, while at others they are so rare as to require close observation for their detection. Voluntary contraction does not suspend them; and they may also appear in other parts not suffering from the disease, as the tongue.

The general economy remains unaffected amidst this slow and progressive muscular destruction; no general symptoms being present, however far the disease may be advanced, and every function being, to all appearance, perfectly performed, except that of voluntary motion.

Duration and Progress.—Although a very long interval may elapse between the first symptoms of weakness and the production of complete muscular degeneration, it is always an invading disease; and once having taken possession of the economy, it never retrogrades; the utmost that can be done being to arrest its course, and that by no means with any certainty. The duration is indefinite, and most of the author's cases came under his notice months or years after their commencement.

Prognosis.—Even in its simplest forms, attacking, as it does, persons of laborious occupations in the prime and vigour of life, it is a terrible disease; and where it involves muscles necessary for important functions, as respiration, it may cause death. Even as an infirmity, in its partial form, there is none more beyond our control.

Diagnosis.—This affection must be distinguished from the paralyses with which it has been confounded. In *paralysis*, if complete, motion is abolished: if incomplete, it is imperfect. In *atrophy*, so long as sufficient fibre remains to raise the levers, motion is performed, though feebly; abolition or incompleteness being thus the character of the one case, weakness of the other. Moreover there is no symptom of disease of the brain or spinal marrow present, and atrophy resulting from paralysis involves the entire limb. The investigations of M. Duchenne show that atrophy from paralysis very rarely gives rise to complete destruction of muscular power. Hysterical paralysis does not lead to atrophy, and the loss of motion is complete. Rheumatic paralysis is not always complete, but it affects the entire muscles of the region. Paralysis from lesion of a nerve is the form which most rapidly gives rise to atrophy; but this is exclusively confined to the muscles supplied by such nerve. M. Duchenne has shown that electrical irritability is intact in hysterical and rheumatic paralysis, even when atrophy is present. In saturnine paralysis, and paralysis from lesion of a nerve, it is entirely lost; while in progressive muscular atrophy, though enfeebled, it exists until the muscular fibre has entirely disappeared. The disease which offers most analogy to it is *progressive paralysis independent of insanity*, in which electricity developes only very feeble contractions, even when the muscles retain their normal size and elasticity. The history of the two affections serves to distinguish them.

Nature and Causes.—It is primarily and exclusively *a disease of the muscular system;* but its etiology is completely obscure. Of the eleven cases, nine were men and two women—the mean age being 36. The occupations were various (as country labourers, stone-cutters, shoemakers), some requiring great muscular exertion, and most of the patients complaining of excess of work; so that the author is disposed to consider the too-continuous and excessive employment of the affected limb as a chief occasional cause; although when we consider the rarity of the disease amongst the hundreds of thousands so situated, this is very problematical.

Treatment, both general and local, has been most assiduously employed, never with the effect of causing the disease to retrograde, and seldom even of arresting it. Galvanism, localised in its action upon the muscles, seems to be the best palliative.—*Archives Générales*, and *Brit. and For. Med. Chir. Rev.*

DISEASE OF THE PANCREAS.

By Dr. Fearnside.

The earliest phenomena noticed were gradual failure of the general health, and faulty digestion; but these symptoms being present in a variety of diseases are of little diagnostic value. *Deep-seated pain in the epigastrium* occurred in both patients, and in both is said to have become aggravated a few hours after taking food. But the importance of this remark is diminished by the signs found after death in one of the cases, of the previous existence of inflammation of the mucous membrane of the duodenum. *Gastrorrhœa* was present in both cases. Some have supposed that the fluid ejected in this affection is a vitiated secretion of the pancreas; but its existence concurrently with such extensive disease of that organ as was found after death, and must have been going on long before that event, when little or no secretion could be eliminated, is adverse to that opinion, and would rather lead us to conclude that it is simply a flux, the result of hyperæmia of the mucous membrane of the stomach, and analogous to the catarrhs of other mucous membranes.

Ptyalism was made the subject of spontaneous complaint by one of the patients. This is a symptom which has been repeatedly observed in cases of diseases of the pancreas, and to which considerable importance has been attached, from some conjectured antagonism or "balancement" between the pancreas and the salivary glands. In the same case in which the last symptom presented itself, the *tongue* was invariably *pale and clean*, and the freedom of this organ from morbid coating in cases similar to those under review, has been made the subject of former remark. *The appetite* was variable; in the case longest under observation, the quantity of food consumed was generally not below the average of health.

The last case also presented a sign upon which some stress has been laid by Professor Siebert of Jena, as evidence of pancreatic disease, when coexisting with other indications,—viz., *abdominal pulsation*. In one of the cases the *action of the bowels* was insufficient, as is stated to be the general rule in these diseases; in the other it was irregular; but in neither case, so far as my observation extended, or I could learn from others, was fatty matter ever present in the evacuations, as noticed by Dr. Bright in certain cases of diseased pancreas. In the case last narrated, the *urine* was repeatedly examined, both chemically and microscopically, but except in being generally scanty, and abounding in lithate of ammonia, it did not deviate from the natural state. *Emaciation* and *anæmia*, present in both patients—in one strikingly—are generally seen in protracted pancreatic disease: in these respects, as in some others, the last detailed history shows a resemblance, almost amounting to identity, in symptoms, with a case related by Dr. Abercrombie. In both, the blood-making functions were greatly impaired, as a consequence of which, and loss of tone in the bloodvessels, there occurred throbbing in the arteries of the head and neck, humming in the ears, and abdominal palpitation. In but one of the cases could any tumour, or fulness of the epigastrium, be recognized during life.

It may be remarked incidentally, that the thoracic symptoms present in the last case were such as have been frequently observed in fatty degeneration of the heart. The dyspnœa, oppression about the chest, tendency to syncope, feeble impulse of the heart, and small irregular pulse, all give evidence of a weakened condition of the central organ of the circulation. The altered character of the sounds of the heart during life was ascribed to the existing anæmia.

From a review of the symptoms met with in these cases, it may be concluded that although none can be stated to be absolutely pathognomonic of disease of the pancreas, yet the union of several affords a very high probability of the existence of a departure from the healthy condition of that organ. In attempting to arrive at a more minute diagnosis, the *general* symptoms and history, with any information derived from a physical examination of the patient, will prove our chief guides. In the case first related the individual had long suffered in a mode which might have led to the opinion that disease of the pancreas existed; then a considerable tumour was found in the situation of that gland: this might have been occasioned by tubercle, cancer, or simple inflammation; the age of the patient, and especially the freedom from pulmonary symptoms, discountenanced the first supposition. More difficulty, however, existed in deciding between the last two, and the absence of any cancerous hue of complexion merely warranted the expression of a probable diagnosis. The sudden accession of acute pain, syncope, and vomiting, followed by jaundice, indicated the occurrence of some change, producing pressure upon the gall-ducts, and from the constitutional sympathy, of a probably disruptive character, but the rarity of pancreatic hæmorrhage prevented the idea of its presence being entertained. In the second case, the group of symptoms, leading us to infer the presence of disease of the pancreas, was more complete than in the first patient. Respecting the nature of the affection it might have been allowable to hazard an opinion from the probable existence of fatty degeneration of the heart.

In the case first related, the pancreas exhibited, on post-mortem examination, a very striking deviation from the natural condition of the organ. The increase in the volume and density of the body and left extremity, was due to a new deposit of matter within its tissue; not in masses, as when this consists of tubercle or cancer, but uniformly diffused throughout its structure. Presenting also none of the other characters of those adventitious growths, it could be referred only to the effusion of exudation matter, the results of inflammation, to the existence of which the state of the peritoneum, and the adhesions to the adjoining parts, abundantly testified. The appearance of the central portion of the gland closely resembled that seen in a case recorded by Mr. Lawrence as one of inflammation. In both the pancreas was of a deep dull red colour, very firm, and crisp on incision. In the left extremity the disease seemed to have been of more ancient date, and afforded many of the recognized characters of old standing inflammation. "When the pancreas has been the seat of chronic inflammation, it is said to acquire a great increase in the density of its tissue, which swells, becomes more dry than natural, and of a reddish and whitish-yellow colour." The head of the pancreas was completely disorganized, and occupied by a mass of grumous blood. Viewed in connexion with the state of the other parts of the gland, there can be no hesitation in regarding the hæmorrhage as the result of softening and ulceration produced by inflammation.

In the second case, the whole substance of the gland was infiltrated with fat, a condition which must be distinguished from mere accumulation of fat between the lobules of the organ. The results of the same vitiated nutrition were also apparent in the fibres of the heart, which presented both the naked eye and microscopical characters of fatty degeneration in a marked degree.

Respecting the etiology of these forms of disease, nothing very definite or satisfactory can be stated. Both patients were predisposed to their occurrence by former intemperance in the use of alcoholic liquors, and from the nature of their occupations—one was much exposed to the weather, the other to sudden and frequent changes of temperature. In the subject of the last case, nutrition had suffered from the employment for some time of an impoverished diet, and the existence of considerable anxiety of mind. But when we attempt to trace further the operation of these causes, granting them sufficient, our light fails us, from our imperfect acquaintance with the nutritive process.

It has been supposed that the obscure disease, diabetes, has an intimate connexion with imperfect primary, especially duodenal, digestion; and Bouchardat has endeavoured to associate it with disease of the pancreas, and consequent depravation or insufficiency of pancreatic secretion. The cases related above, however, afford no countenance to that opinion. Although, for some time before

death, the gland must have been functionally inactive, yet in the case longest under observation, the urine showed no change from its natural condition, except in occasionally being scanty, concentrated, and depositing urate of ammonia.—*Med. Gaz.*

ON BELLADONNA AS A REMEDY IN SCARLET FEVER.

By Dr. John Gardner.

Belladonna has been chiefly used as a *prophylactic* where the poison of scarlet fever was likely to be effective. But it has not often been used when the attack has commenced. Some authors have pronounced it decidedly prophylactic, and others, among whom is Dr. Pereira, have doubted this power. It is very justly argued, that twenty cases of failure are more conclusive than hundreds of non-occurrence of the disease after its exhibition. Dr. Gardner supposes that as belladonna was recommended by Dioscordes as a remedy in erysipelas, the analogy of the two diseases must have led many men to employ it in scarlet fever. He says:—

The analogy of scarlet fever in its malignant form with erysipelas, together with our knowledge of the powerful and peculiar influence of belladonna on the nervous system, render it worthy of a full and fair trial. Accordingly, I proceeded to try it, giving it in efficient doses, and taking care that the preparation I administered was in a proper state. The latter precaution is at all times necessary, because, while the extract, if properly prepared and preserved, is highly efficient, it is often found in the shops, either from being badly prepared originally, or from long keeping, wholly inert, so that half an ounce has been given for a dose without any effect. Happily, we have a very excellent and easily applied test for the activity of the extract of belladonna: a grain or two rubbed on the eyelids should, in a minute or two, produce full dilatation of the pupil.

In all my cases up to the present time, I have used extract of belladonna which was prepared at Apothecaries' Hall, some four or five years old, but it acts immediately on the pupil, whether applied externally or taken into the stomach.

Without reckoning slight cases of scarlet fever and sore throat, I have treated upwards of thirty cases, with symptoms more or less grave, by means of the belladonna. In very many of these cases I should formerly have entertained no hope of seeing the patient pass through the attack, the approach of the disease being marked by a malignant aspect. I need not enumerate the peculiar symptoms which characterize fatal scarlet fever—these are well known to every practitioner. In the absence of the belladonna, I have watched with great anxiety these fatal tokens: they allow little room for our anticipations being negatived. But with the belladonna I have not yet met with a fatal case.

Moreover, it is well known, that in no inconsiderable proportion of cases, whether severe or slight, very inconvenient sequelæ occur on the subsidence of the fever, arthritic pains, œdema of the extremities, anasarca, and even hydrocephalus. In no case treated with belladonna have I met with such sequelæ.

I administer the belladonna according to the ability of the patient to bear it, in doses of half a grain to a whole grain every three, four, or six hours, dissolved in water; the dilatation of the pupil and the amount of stupor produced, being the basis of discrimination. I do not allow low delirium even from the first, nor indeed any other symptom, to deter me from giving belladonna, but I give no other medicine whatever, except an occasional dose of castor oil to secure a daily action of the bowels.

There is, of course, no objection to the concurrent use of other items of treatment: removal of the hair, cold affusion over the head, and sponging the limbs and body if it can be borne, gargles of the chlorides or mineral acids, &c.; but I depend little on any of these.

The diet I have usually recommended has been bread and milk, never depending upon mere farinaceous foods, so as to withdraw all, or most, of the nitrogenous principles from the food—a practice I believe to be fraught with danger.

Making every allowance for the many sources of fallacy necessarily incident to the uses of a remedy under the circumstances of this example, I know nothing in the whole compass of medicine in which I have more confidence. I have recommended this plan of treating scarlet fever to several friends, and their reports of its effects have been uniformly favourable.

It would be out of place here to enter upon speculations as to the *modus operandi* of the belladonna, or any other collateral topic relative to the disease, my present object being simply to state the results of my own experience of the power of belladonna, and to request, on the one hand, any of my readers who may have fallen on the same plan to publish the results they have observed; or on the other, to recommend the trial to those who have not hitherto employed it, without regarding the folly of the homœopathists.

In conclusion, I would suggest, that to obviate the uncertainty necessarily attendant upon the use of the extract of belladonna, the alkaloid atropine, or some of its salts, should be tried. The sulphate of atropine is, perhaps, the best. It is soluble in water, stable, and in every way manageable. I have not, however, at present prescribed this salt.

Mr. T. J. Green of Peckham, corroborates the above communication of Dr. Gardner, as to the value of belladonna in scarlet fever. He says:—

"The preparation I have used for ten years is the Apothecaries' Hall powder; the colour, aroma, and virtues of this, will, in a dark-green bottle, keep for years. The dose I have always given to persons above puberty is one-sixth of a grain in mint water, every four hours. For children, I rub one grain with five grains of powder of liquorice-root, and of this, give one-sixth or one-twelfth of grain in water, every four hours. For infants it should be used in extremely minute doses, as it sometimes, in my opinion, brings on spasm of the larynx, and kills the child. A gargle of the sulphate of copper, one grain to one ounce of warm water, or camphor mixture, used every hour, is very good."—*The Institute.*

USE OF TOBACCO AND INDIAN HEMP IN EGYPT.

I cannot deny myself the pleasure of adverting to Dr. Mussey's widely-promulgated anathemas against the use of tobacco, the habitual use of which is as much objected to by myself as by that staunch apostle of temperance in eating, drinking, and smoking. But with all his zeal, his philanthropy, his bold arguments and cogent reasoning on this subject, in Egypt he would find stumbling-blocks in the way of his conclusions that would be worse to manage than a hogshead of the best Kentucky in the market. Men, from childhood, smoke incessantly in Egypt. They smoke everywhere and under all circumstances. There is no cessation—not an hour when a cloud of curling smoke is not ascending. It is the first and prominent civility to hand a pipe, and smoke you must, or suffer under the imputation of being no gentleman; and were that good man of Cincinnati sitting where this sentence is written, he would find himself smoke, like every one else here. People live long enough, in all conscience, notwithstanding this everlasting smoking; for they outlive their usefulness—outlive everything but animal wants—live, some of them, till everybody wishes they were dead! I have not been an inattentive observer of the smoking mania in Germany and other parts of continental Europe; on the contrary, a strict inquiry into the moral and constitutional effects of the habit, very judiciously called a vice, was instituted as I travelled from kingdom to kingdom where it prevailed; and I have arrived at the gratifying conclusion, that if persons wish to smoke they may, and I shall not waste my breath in warring against the habit. Another kind of

smoking is practised in Egypt, and probably in Syria, unknown to us in America—viz., that of Indian hemp. Cigars are charged with it, and there are apartments where individuals may go, and draw in, through a long pipe-stem, a kind of smoke that exalts a dirty bare-footed rascal into an imaginary prince. In a few minutes he sees the gates of a Mohammedan paradise, gazes wildly towards the sky, and laughs till all consciousness passes away, and he falls into a lethargy of considerable duration. I suspect it is hemp, and not opium, as generally supposed, with which cigars are drugged, and made the instruments, in the hands of designing men, in London and other great cities on the Continent, for the perpetration of many dreadful crimes.—*Letter from Dr. J. V. C. Smith, in Boston Medical and Surgical Journal.*

FRACTURE OF THE ANTERIOR PORTION OF THE OS CALCIS.

By W. S. W. Ruschenberger, M.D., Surgeon, U.S.N.

On November 24, 1850, Lieutenant W——, aged 32, athletic, weighing 190 pounds, while in a paroxysm of mental aberration, attempted to escape from the United States Naval Hospital, New York, where he had been confined as a patient for several days. Between seven and eight p.m. he leaped from the top of a wall, which encloses the grounds, at a point where it is fifteen feet high, and alighted upon his soles on the hard gravel-paved side walk of the street. At the time he was in a dressing-gown and slippers.

He was unable to rise upon his feet. Some passers-by conveyed him into a neighbouring grog-shop, where I examined him about ten minutes after the fall. It was stated he was insensible when picked up, and that he had swooned after he was placed in a chair. When first seen by me, he was very pallid and faint; he expressed his opinion, formed from a sense of pain alone, that "all the bones of his feet were crushed." Both ankles and feet were contused. Distinct crepitus was heard on moving the left foot. Below the malleolus externus and a little anterior to the axis of the fibula, was a tumour or projection, caused by a fragment of bone, estimated to be about a cubic inch in size, which was seized between the thumb and fingers, and moved easily but not extensively beneath the skin. Moving this fragment caused distinct crepitus and severe pain. The toes and metatarsus could be turned inwards, on a plane with the sole, almost to a right angle, owing to a relaxation or partial separation of the metatarsal from the tarsal bones. There was nothing abnormal observed in the motions of the astragalus upon the tibia. There was no displacement of the posterior extremity of the os calcis; but the patient stated subsequently that when his consciousness returned, he found the heel bone drawn up out of place. There was no fracture of the fibula or tibia. Pressure posteriorly to the cuboid showed an unusual yielding space in that region. The patient was conveyed to his bed in the hospital, complaining considerably of pain. Cold water dressings were applied to the feet and ankles; and a fourth of a grain of meconate of morphia in solution was administered. The bowels had been moved twice during the day.

25th. Ankles and feet considerably swollen, ecchymosed, and very painful. Cold water dressings and meconate of morphia at night. 27th. Has less pain; passed a better night; seemed quite rational. Continue treatment. 28th. Appears to be perfectly sane; better; persist. 29th. Swelling and pain of ankles less. Continue treatment. 30th (sixth day after accident). Left ankle and foot carefully examined this morning; the anterior and external portion of the os calcis, which articulates with the os cuboides, was fractured and separated; the fragment lying below and projecting externally beyond the malleolar process of the fibula; firm steady pressure by the thumbs, directed forward and inward, reduced it, the fragment suddenly slipping into place. A roller was turned firmly around the foot and over a compress placed upon the fractured portion. The entire leg and foot were then encased in felt, previously softened, and the whole dressing retained in place by a roller.

December 2nd. From the instant the fracture was reduced, he has had no pain in the foot; he seems to be of sound mind. Although unable to bear either foot in a pendant or vertical position without discomfort or pain, Lieutenant W., at his own earnest request, was conveyed to his home. The patient, who is restless and restive in disposition, very soon moved about, and has recently visited Washington City; I have been told he is not lame.

Remarks.—The history of the above case of rare fracture is derived chiefly from notes by Assistant-Surgeon Gould of the United States Navy, who was associated with me on duty when it occurred. The accident was probably caused by the sole of the foot coming in violent contact with some inequality, such as a small pebble, opposite to the anterior extremity of the os calcis. About a week after this fracture, a boy, aged 17, weighing probably less than one hundred pounds, attempted to desert, and leaped the wall at the same point. In his case there was severe contusion and sprains of both ankles, but no fracture. He was able to limp away nearly a half mile. The influence of the meconate of morphia, as far as it could be determined by administration in the above and one or two other cases, does not differ remarkably from that of the other salts of morphia.—*Phil. Med. Ex.*

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, AUGUST 6, 1851.

COMPRESSION *versus* THE LIGATURE.

We have so frequently had occasion to report the failures of compression in the hands of London Surgeons, that it gives us much pleasure to be able *at length* to quote a case of popliteal aneurism brought to a successful termination by this method of treatment in a metropolitan hospital.

Every one who has paid attention to the subject, must have been struck with the difference in the treatment of aneurism in the two countries; thus in the Dublin Hospitals, compression, as a general rule, is employed in every case of femoral, popliteal, or brachial aneurism to which it is adapted: in the London Hospitals, on the other hand, the employment of compression forms the exception to the general rule. Again, while almost every trial of compression in the Dublin Hospitals has been attended with success, almost every case in which compression has been attempted in the London Hospitals has proved a failure.

What are the causes of this difference? Surely there is none in the disease, which is equally amenable to compression in the one country as the other; and is equally liable to be followed by disastrous results, whether treated in a London or a Dublin hospital, by the ligature. If the two modes of treatment were equally free from risk, we should not quarrel with the surgeons of one locality for preferring one method of treatment, or with those of another for preferring another mode; but when experience teaches, and statistical results prove, that one of these methods of treatment is attended with considerable risk to life, while the other is unattended by any risk, we must ask—is it humane, is it just to the poor patients whose necessities compel them to seek admission into a public hospital, to continue to employ a mode of treatment which has been proved to be the cause of death in very nearly one of every six patients submitted to it; and to refuse to employ a mode of treatment in the same disease which experience and statistics both prove to be unattended by any risk whatsoever?

The question is now no longer one merely as to which is the most convenient method, which causes least pain, or in which the duration of the treatment is the longest; but it is—and it is necessary that it should be stated plainly—a question where the life of a human being is concerned, who puts himself under the care of a surgeon with the conviction that he will use not only the most effectual but the safest means for his cure; and that he is likewise competent to do so.

It has been over and over again proved, that compression, even with imperfect instruments, will succeed in curing aneurism; that when judiciously employed, and carefully carried out, it must, from the manner in which it acts, effect a cure in every case to which it is adapted; and moreover, that its use is not attended with the slightest risk to the patient. It will therefore no longer answer for the surgeon to endeavour to shelter himself behind the plea that he has no experience of this method; it is his duty to acquire the necessary experience. If it is obligatory upon him to study the anatomy of the femoral artery in order to enable him to place a ligature upon this vessel, when such a proceeding is called for, it is no less his duty to make himself familiar with every point connected with compression of the same artery, in order that he may be able to apply pressure correctly and efficiently, and thus to bring about the cure of a popliteal or femoral aneurism: which, if he is incapable of doing, he is not fit to occupy the post of surgeon to a public institution, where such cases are liable at any moment to present themselves.

We shall probably again recur to this subject. In the meantime, we place on record in our pages a successful case of popliteal aneurism treated by compression in a London hospital, and we venture to express the hope that it may be the prelude to many others of a similar nature from the same quarter.

AN ACT TO REGULATE THE SALE OF ARSENIC.

We copy this important act, although it has not been called for in consequence of delinquencies in this country, because it will be the duty of surgeons to see that it is carried into effect notwithstanding. It is a very remarkable illustration of the operation of that legal maxim, *de minimis non curat lex*. As long as a reasonable number only of people were poisoned, no notice was taken, but when the crime became a common one, and the consequences frightful, an act was passed without difficulty. Had this been done even five years ago, how many might have been saved from a sudden and painful death, and how many from the gallows? Year after year the medical journals called for legislative interference in vain, until the evil began to alarm people for their own safety. Had there been "a post," a commissionership, or something of that kind to be created, how different would have been the result:—

Whereas the unrestricted sale of arsenic facilitates the commission of crime: be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present parliament assembled, and by the authority of the same, as follows:—

1. Every person who shall sell any arsenic shall forthwith, and before the delivery of such arsenic to the purchaser, enter or cause to be entered in a fair and regular manner, in a book or books to be kept by such person for that purpose, in the form set forth in the schedule to this act, or to the like effect, a statement of such sale, with the quantity of arsenic so sold, and the purpose for which such arsenic is required or stated to be required, and the day of the month and year of the sale, and the name, place of abode, and condition or occupation of the purchaser, into all which circumstances the person selling such arsenic is hereby required and authorized to inquire of the purchaser before the delivery to such purchaser of the arsenic sold, and such entries shall in every case be signed by the person making the same, and shall also be signed by the purchaser, unless such purchaser profess to be unable to write (in which case the person making the entries hereby required, shall add to the particulars to be entered in relation to such sale, the words "cannot write"), and, where a witness is hereby required to the sale, shall also be signed by such witness, together with his place of abode.

2. No person shall sell arsenic to any person who is unknown to the person selling such arsenic, unless the sale be made in the presence of a witness who is known to the person selling the arsenic, and to whom the purchaser is known, and who signs his name, together with his place of abode, to such entries, before the delivery of the arsenic to the purchaser, and no person shall sell arsenic to any person other than a person of full age.

3. No person shall sell any arsenic unless the same be before the sale thereof mixed with soot or indigo, in the proportion of one ounce of soot or half an ounce of indigo, at the least, to one pound of the arsenic, and so in proportion for any greater or less quantity: Provided always, that where such arsenic is stated by the purchaser to be required, not for use in agriculture, but for some other purpose for which such admixture would, according to the representation of the purchaser, render it unfit, such arsenic may be sold without such admixture, in a quantity of not less than ten pounds at any one time.

4. If any person shall sell any arsenic, save as authorized by this act, or on any sale of arsenic shall deliver the same without having made and signed the entries hereby required on such sale, or without having obtained such signature or signatures to such entries as required by this act, or if any person purchasing any arsenic shall give false information to the person selling the same in relation to the particulars which such last-mentioned person is hereby authorized to inquire into of such purchaser, or if any person shall sign his name as aforesaid as a witness to a sale of arsenic to a person unknown to the person so signing as witness, every person so offending shall for every such offence, upon a summary conviction for the same, before two justices of the peace in *England* or *Ireland*, or before two justices of the peace or the sheriff in *Scotland*, be liable to a penalty not exceeding twenty pounds.

5. Provided: That this act shall not extend to the sale of arsenic when the same forms part of the ingredients of any medicine required to be made up or compounded according to the prescription of a legally qualified medical practitioner, or a member of the medical profession, or to the sale of arsenic by wholesale to retail dealers, upon orders in writing in the ordinary course of wholesale dealing.

6. In the construction of this act, the word "arsenic" shall include arsenious acid and the arsenites, arsenic acid and the arseniates, and all other colourless poisonous preparations of arsenic.

MEDICAL CHARITIES' BILL.

We can, we believe, with safety say that the bill may be considered as passed; having reference, as we have already said, to Dispensaries only. We, however, refrain from comments on it until we can lay the act in full before our readers. The less that is said about any causes, whatever they may have been, which led to the enactment in its present form, the better. It is clearly the interest of every practitioner in Ireland to promote the quiet and effectual operation of the measure; for as surely as the members of our profession, in consequence of any jealousies or conflicting interests, obstruct its operation, so surely will the natural enemies of the medical institutions avail themselves of the opportunity.

PARLIAMENTARY GRANTS TO COLLEGES OF SURGEONS.

HOUSE OF COMMONS.—JULY 18.

On the vote for £15,000, for 1851, towards the erection of an additional museum, and for enlarging the theatre of the Royal College of Surgeons, for the delivery of the Hunterian lectures,

The Chancellor of the Exchequer said, many years ago Mr. John Hunter, the most celebrated surgeon, perhaps, which this country ever produced, accumulated a collection of anatomical specimens of great value, which eventually became so extensive and valuable, that they were bought by the country, and ultimately committed to the care of the College of Surgeons. Since that museum had been committed to their care, the College of Surgeons had most faithfully discharged the trust reposed in them. They had themselves greatly added to the museum at a cost of no less than £189,000, and thrown it open to the public. Having

spent that very large sum of money, which they were not bound to do, they found themselves without adequate funds to enlarge the museum and theatre as was their wish. Under these circumstances, they had applied to the government for assistance, and the government proposed to grant them £15,000 with that view, to which he trusted the committee would give its assent.

Colonel Dunne and Sir R. Inglis each supported the vote, which was agreed to without a division.

This is as it should be, but let us have no grumbling about similar grants, if any there should be, to such institutions in Ireland. It is quite clear that this department of the public service cannot be properly conducted on the voluntary principle, and this, with other recent arrangements for medical education at the public expense, proves it. It remains, however, to be decided in what proportions the funds allocated by the state for this purpose are to be distributed amongst the educational institutions. The restriction of them to any particular colleges or hospitals will not be tolerated.

THE "VITAL STATISTICS" OF THE CENSUS.

We copy the following from a London contemporary, to whom it has evidently been "communicated" by a party concerned. The "touch of the pathetic" with which it concludes, tells the source from which it emanates. There are evidently symptoms of misgivings as to the results. It seems that there are "sources of fallacy" which may render the "vital statistics" of doubtful value:—

It is true, as already mentioned, that the commissioners, Messrs. Donnelly and Wild, have asked in their returns for the number of deaths which occurred in each family since the last census; but how many are the families who have been altogether carried off, and for whom there can be none to answer? This source of fallacy must not be forgotten in any attempt at an estimate of the number of deaths in Ireland since the last census. The facts, we repeat, are simple; not so the explanation of the desolation of one of the most fertile countries in the world, and one occupied by a people from whom, whatever may be the habits and characters of the majority, have sprung some of the brightest ornaments of every phase of public and professional life. Let us hope that it may never again fall to our lot to dwell on a catastrophe so deplorable.

THE LAW OF LUNACY.

On Thursday, the 17th ult., a meeting of the "Association of Medical Officers of Hospitals for the Insane" was held by appointment, at twelve o'clock, at Freemasons' Tavern. Dr. Conolly, being the senior member of the association, was voted in the chair. The following members, with others, were present:—Dr. Bucknel of the Devon Asylum; Dr. Huxley, Kent Asylum; Dr. Stewart, Belfast Asylum; Dr. Mirtle, Asylum, Oxford; Dr. Kirkman, Suffolk Asylum; Mr. Diamond, Surrey Asylum; Dr. Boyd, Somerset Asylum; Mr. Prosser, Asylum, Leicester; Dr. Fox of Northwoods; Dr. Munro of Bethlem; Dr. Lloyd Williams, Dr. Winslow, Mr. Mallam, and Dr. Nesbitt of the Northampton Asylum.

The association has been in operation some years. Its meetings have hitherto been held in the provinces, at or in the neighbourhood of the various county asylums. It was, however, determined this year to summon a meeting of the association in London, in order to afford the members living in the metropolis an opportunity of discussing with their provincial friends some important matters of business. As a preliminary matter, the question arose as to the organization of the society. The association has always met annually in the provinces, and has been confined to medical gentlemen officially connected with county or public lunatic asylums. It was proposed and carried, that medical proprietors of private asylums should be eligible as members; and a number of gentlemen were immediately elected. It was also resolved, that, for the future, the annual meetings should take place in London, in the second week of July, and that the members of the association resident in and near London, should hold quarterly meetings in the metropolis for the despatch of business. The condition of the criminal lunatics was then brought under the notice of the society by Dr. Conolly, and after a long discussion, in which Drs. Boyd, Nesbitt, and Winslow took a part, it was agreed to present a petition to government for the establishment of an institution apart from Bethlem, exclusively for the reception of persons acquitted of crime on the plea of insanity. The unfortunate, desolate, and unhappy condition of the criminal lunatics was feelingly dwelt on by all the speakers, and it appeared to be the unanimous opinion of the association that sufficient attention has not been paid to their state. It was thought that great good would result from the separation of the criminal from the other lunatics confined in Bethlem and other public asylums. The state of the laws relating to the insane was then fully discussed. It appeared to be the opinion of the association that the lunacy acts were greatly defective, and that the whole of them required careful revision. Nearly all the speakers pointed out most glaring errors in the construction of the acts of parliament bearing upon the management of asylums and the care of the insane. It was proposed that a committee of five members of the association be formed to consider the subject. The following gentlemen were nominated:—Dr. Corsellis, Dr. Conolly, Dr. Forbes Winslow, Dr. Boyd, and Dr. Nesbitt. It was also proposed and carried, that Dr. Winslow should be appointed secretary to the committee; that he should communicate with the various members of the association, and obtain from them their suggestions as to the amendment of the law, and embody them, with his own views, in an official shape, for the consideration of the government and the commissioners in lunacy. The inquiry which Dr. Winslow was authorized by the association to make was to extend to all the lunacy acts, embracing also the enactment relating to the administration of the property of lunatics, which was considered unjust and defective in its operaton. After the despatch of other business, the association agreed in a body to visit Colney Hatch and the Surrey County Asylum, with the view of inspecting their arrangements. The first quarterly meeting of the association is to be held in London early in September, when important matters of business are to be considered.

RESULTS OF HOMŒOPATHY.

The unfortunate subject of the Norwich consultation has died, after protracted sufferings. The following is a brief notice of the termination of her case, written by Dr. Copeman, with Mr. Donald Dalrymple's account of the subsequent autopsy:—

"Since I last addressed you, the patient who was the subject of my former communication had an attack of phlegmasia dolens, which terminated fatally. A post-mortem examination was made in the presence of Mr. Firth, Mr. Cooper, and myself, by a gentleman entirely unconnected with the treatment of the case, and who had not witnessed its progress. I now forward you his statement of appearances after death, reserving further observations for a future occasion, when, probably, for the benefit of medical science, and without any view to personal crimination, I shall lay before the profession the whole history and treatment of the case, with such remarks as may appear necessary to elucidate the true pathology of it, in contradistinction to that which has been propounded by Dr. Murphy, and used, to the prejudice of another practitioner, by the party who summoned Dr. Murphy in consultation.—I remain, &c.,

E. Copeman, M.D.

Account of the post-mortem examination of Mrs. Gladstone, performed by Mr. Dalrymple on the 1st of July, 1851, nine hours after death.

The general appearance of the body did not exhibit material emaciation; there was considerable œdema of the left thigh, leg, and labium.

Thorax.—A small quantity of serum in both pleural cavities; lungs perfectly healthy; heart covered with fat, and flabby; blood very thin and serous; the coagula very soft, and deficient in fibrin.

Abdomen.—The liver large and soft; the inferior surface of the left lobe spotted with several patches of ecchymosis, as if slightly bruised; intestines pale, and distended with air; spleen healthy; stomach large, and filled with viscous fluid; the mucous membrane very soft, pale, and the coats of the stomach extremely attenuated in the situation of the large end beyond the cardiac opening.

Pelvis.—The bladder partially distended with urine; the transverse diameter of the uterus, as seen *in situ*, an inch

longer than natural; surface very pale; both ovaries mottled and firm. The rectum was somewhat distended, and dark on the right side, behind the posteror surface of the uterus. The left spermatic vein contained a coagulum several inches long, and near the ovary, of sufficient size and firmness to completely plug up the vein, the clot itself being tubular, and containing purulent matter. The left common iliac vein was filled with a large quantity of bloody pus, of a sour putrid smell. The kidneys large and healthy, but exhibiting the same signs of complete anæmia as the rest of the body. The vagina was entire as to its mucous membrane; the posterior wall of a deep pink hue. The posterior lip of the os uteri exhibited a line of slough, about half an inch long, by two or three lines in breadth; the rest of the circumference of the os uteri was inflamed, but not sloughy. The cavity of the uterus was filled with pus, proceeding from an abscess of considerable size in one of the sinuses of the uterus, near the entrance of the left Fallopian tube, the edges of the abscess projecting somewhat into the uterine cavity. The lining of the uterus was sloughy, but between the line of slough of the os uteri and that of the cavity of the uterus, there was a surface of membrane three-quarters of an inch long, free from slough, indicating that the sloughy state of the two portions had separate origins. The condition, indeed, of the os uteri was that of an organ that had been extensively injured, and which had been considerably repaired by nature. The mucous membrane around the entrance of the right Fallopian tube was also slightly projecting and sloughy. The left uterine and hypogastric veins were plugged by tubular clots."

Our readers will form their own opinion of the connexion between the long-continued and forcible dilatation of the os uteri by the homœopaths originally in attendance upon the case, and the sloughing of the os and cavity of the uterus, and the phlebitis and purulent deposits in the neighbouring veins. In this contribution to obstetric pathology, we have a clinical exposition of homœopathic practice in threatened abortion accompanied by profuse hæmorrhage. We learn that the homœopathic trick is, to administer globules, or, in other words, to do nothing whatever in the way of medical treatment for the arrest of hæmorrhage, or to excite the expulsive action of the uterus. But to make up for this inertia, the most martial mechanical appliances are resorted to. We trust it may be long before we have to record a similar case; but when we do, let us hope that the whole honour or odium may rest with the homœopaths themselves, and that no professional authority may be found to justify or excuse proceedings which admit neither of justification nor excuse.—*Lancet.*

BIRTHS AND DEATHS IN LONDON,

DURING THE WEEK ENDING SATURDAY, JULY 26.

Births.		Deaths.

THE MEDICAL CHARITIES' BILL.

At a Meeting of the Acting Committee of the Physicians and Surgeons of the Irish Fever Hospitals and Dispensaries, held in pursuance of public notice at the Hibernian Hotel, Dublin, on the 31st of July, 1851,

Dr. Kingsley in the chair,

After hearing the report of their Secretary, Dr. Knox, the following resolutions were passed unanimously:—

I.—That the report just read, be approved of and adopted, and that the best thanks of the committee are justly due and hereby given to Dr. Knox, for his prompt and unremitting exertions, both as our honorary secretary and accredited agent in London, to advance the interests entrusted to his care.

II.—That our best thanks be also given to the Right Honourable Sir William Somerville for the uniform courtesy we have experienced from him, and for the readiness with which he has at all times taken into consideration such suggestions as were made to him through our Secretary, for the introduction of several decided improvements in the Medical Charities' Bill, as well as for his firm and successful resistance of certain proposed alterations of a very objectionable tendency; and although we feel deeply disappointed that the pertinacious opposition he has met with has, for the present, prevented his carrying in its integrity a bill of such great social importance, we have the fullest confidence in the assurance he has given that he will endeavour to render the law uniform and complete by bringing forward an Hospital Amendment Bill in the ensuing session of parliament—a measure so urgently required, both in policy and justice, as to leave no doubt of its ultimate success.

III.—That our Secretary having reported to us the active and valuable assistance he has at all times received from Dr. Maunsell, especially whilst coöperating with him in London, we request his acceptance of our best thanks; and we beg leave to acknowledge at the same time the promptitude with which the Council of the Dublin College of Surgeons have on several occasions acceded to our request by sending their Secretary to London to look after our interests.

IV.—That our Secretary be empowered to convey the acknowledgments of the committee to those members of parliament who sincerely and zealously supported Sir William Somerville in his persevering attempts to carry the bill in a perfect form.

V.—That the report of the proceedings of the committee up to the close of the present session of parliament, be printed with as little delay as possible, and circulated amongst the subscribers to the Medical Charities' Bill Fund, with an abstract of the treasurer's account, which, together with the vouchers, has now been produced, audited, and found correct.

VI.—That our resolutions be published in the ensuing number of the Medical Press.

Signed,

William Kingsley, M.D., Chairman.

John Waters, M.D., Secretary, *pro tem.*

The committee subsequently formed themselves into a meeting, according to public notice, open to all subscribers, to give any detailed information of their proceedings that might be required.

Alexander Knox, M.D.,

Honorary Secretary to the Acting Committee.

DISPENSING OF MEDICINE.

G. OLDHAM and CO.,

Pharmaceutical Chemists, and Apothecaries,
From Bewley and Evans',
No. 107, Grafton-street, Dublin,
(Corner of Suffolk-street),

Beg to return their grateful acknowledgments to the Medical Profession for the support they have hitherto received, and which they will regard as a fresh motive for exertion. Abstaining altogether from visiting as Apothecaries, except for the application of Leeches, Cupping, and such operations as are performed under medical advice, they will continue to devote themselves exclusively to the duties devolving on the pure Pharmacien.

Having had much experience in Practical Pharmacy, and being resolved to spare neither trouble nor expense in order to have every article of superior quality, they hope by attention, "carefulness," punctuality, and moderation of charges, to commend themselves to the approbation of those who may entrust them with their commands.

☞ *G. O. and Co. invite attention to their present stock of Surgical Instruments, all of which are manufactured on the most modern and improved principles.*

QUALIFIED SURGEONS FOR SHIPS.

The London and Provincial Medical Protection and Benevolent Society, 43, Lincoln's-Inn-Fields, London, provide Emigrant and other Ships with Medical Officers. Gentlemen desirous of obtaining appointments may be provided with particulars by communicating with the Liverpool Agent, Mr. William Webb, Union Court, Castle-street, Liverpool.

HISTORICAL SKETCH OF THE CONNEXION OF ASTROLOGY WITH MEDICINE.*

By M. Donovan, Esq., M.R.I.A.

In the following sketch it is not my intention to give an account of the doctrines of astrology, but merely to notice the dangerous extent to which they had pervaded the healing art during the early and middle ages; and to show, by the universality of the delusion, that the medical profession, unless in some especial cases, was no more censurable for its adoption than mankind in general. The population of the world had been born and educated in the belief of the reality of these ridiculous doctrines; the delusion of the medical faculty was shared with the most learned and exalted—with kings, nobles, statesmen, and philosophers, nay, even with the clergy, who should have sooner perceived that astrology sapped the foundation of religion.

Astrology was, in the early periods of its history, identified with the most sublime of all the physical sciences: he that studied astronomy studied astrology; and to be able to separate the real from the imaginary was the good fortune of after ages only. In process of time, the objects of the science of the heavens were perverted, and an art arose which professed to foretel events by the aspect of the stars. When it was believed that "the heavens are one great book wherein God has written the history of the world, and in which every man may read his own fortune and the transactions of his time," such a study was no doubt a subject of curious interest to any one who believed himself an object of such consideration in creation that even the very stars were occupied in disclosing his fortunes and directing his fate. It would, then, be prudent that physicians should pursue the study of judicial astrology, as the new science was called; for he who, beside treating the sick, could predict the result of the disease, and determine, by an infallible guide, the proper moment for each step of the cure, must have irresistible claims to preference. Accordingly, from the time of Hippocrates down to a comparatively late period, physicians have been more or less tinctured with astrological notions. At one period, astrology was a branch of medical education, of such importance, as was supposed, that none were considered competent physicians who were not also eminent astrologers.

The art of predicting future events from the aspect of the heavens, as might be expected, has been attributed to various persons, countries, and ages: the astrologers, availing themselves of a statement of Josephus, refer the origin of their art to the most remote antiquity. According to the Jewish historian, the sons of Seth, who were the inventors of the wisdom of the stars, having learned from the prediction of Adam that the world would be destroyed twice, by water or fire, the fear that their discoveries might be lost before they were sufficiently known, induced them to build two pillars, one of brick and the other of stone, on which they inscribed the knowledge they possessed, to the end that if the pillar of brick should be destroyed by the flood, the pillar of stone might remain and exhibit their discoveries. The pillar of brick still existed in the time of Josephus. This mode of preserving knowledge was afterwards extensively employed in the ancient world. (Antiquities of the Jews.)

According to Plutarch, astrology owes its origin to Zoroaster,—the best supported opinion is that the Chaldean Zoroaster, the founder of the Magi, was the person. The Athenians attributed the invention to Berosus the Chaldean, priest of Belus, who wrote a history of the deluge, and collected the works of astronomy and philosophy known amongst the Greeks. He was the first that calculated nativities. The Athenians erected a statue to

* The proprietor of the Dublin Medical Press has suggested that the interest of this sketch would be increased by insertion of the authorities from which the facts have been derived. In my former communication, relative to the iatrochemists and alchemists, I, for the most part, omitted the authorities, in order to save space; I have now subjoined them whenever I found them appended to the notes which I have taken occasionally during several years from works in the public libraries of England and Ireland, and from others obtained through private sources.

his memory—an honour granted only to the most eminent public benefactors. Ptolemy declares the invention is due to the Egyptians and Babylonians; but Lucian gives it to the Ethiopians; others, again, to the Assyrians—from all of which it may be safely inferred that nothing is really known on the subject.

There is evidence of a belief in this fallacious science amongst the Egyptians at a period of remote antiquity: four of the forty-two books of Hermes were devoted to it. The magnificent sepulchre of Osymandyas, a king of Egypt, who reigned about thirteen centuries before the Christian era, contained a circle of gold 365 cubits in circumference, and one in thickness, on which were engraved the rising and setting of the stars and their portents. In the sepulchre were deposited 20,000 volumes; and a colossal statue seventy-five feet in height and twenty-three feet across the shoulders, the whole hewn out of one block of granite, declared the greatness of the monarch in the following inscription:—"I am Osymandyas, King of Kings. If any one desires to know what a prince I am, let him exceed my exploits." This beautifully sculptured tomb is now a ruin: the statue is broken into fragments. (St. John's Travels.)

Amongst the Egyptians none could be priests unless persons well versed in astrology; their kings must also have been astrologers as they were elected from the college of priests.

The poem of Manetho, the historian of Egypt in the middle of the third century, is said to have been chiefly occupied with astrology. Ptolemy, the astronomer, wrote on the same subject a century previously. The Emperor Severus, a man of learning and superior understanding, did his utmost, while in Egypt, to suppress both astrology and magic, but failed.

All measures of state policy amongst the Babylonians and Lacedemonians were counselled by the astrologers. It was the advice of Aristotle to Alexander that he should not undertake even the ordinary occupations of life without consulting persons skilled in the art; yet this occasionally sagacious monarch, when at Babylon, acted in direct opposition to them.

Amongst the ancient Chinese, many centuries before our era, the state astronomers, who were also astrologers, were responsible with their lives for failure in foretelling eclipses. Their notion of an eclipse of the sun was that a monster was then devouring it. Astrology was of high importance, being connected with the politics of the nation. Confucius wrote a treatise on the subject. When the Emperor Tsin-chi-hoang, about two centuries before CHRIST, burnt all other books, he spared those on astrology, medicine, and agriculture.

With the ancient Mexicans astrology was in high estimation. "In no country, not even in ancient Egypt, were the dreams of the astrologer more implicitly deferred to. On the birth of a child he was instantly summoned. The time of the event was accurately ascertained; and the family hung in trembling suspense as the minister of heaven cast the horoscope of the infant, and unrolled the dark volume of destiny. The influence of the priest was confessed by the Mexican in the very first breath which he inhaled." (Prescott, Conquest of Mexico.)

Tiraboschi (Storia della Letter. Ital.) says that he finds no mention of astrologers in Rome until the year 614, U.C.,* in which year the prætor commanded that within ten days the Chaldeans should quit the city—men who, with deceptive observation of the stars, "concealed their falsehoods in profitable mystery." Twice during the reign of Augustus they were ordered to quit Rome; but edicts are insufficient to extirpate superstition, and there were always in that city impostors of this kind and their dupes. The emperors themselves made use of both, nay, practised astrology, or, as it was then called, "mathematics." Domitian dabbled in it; Alexander Severus commanded the establishment of a public school of astrology, notwithstanding his efforts to suppress the art in Egypt; Adrian foretold his death and all the events of his life by astrology; Tiberius, himself an adept in astrology, banished the whole tribe of astrologers, yet for his own service he retained Thrasyllus, a Rhodian, well versed in the art and in the sciences, and received his predictions every day: Thrasyllus had predicted the period of the death of Tiberius. The emperor having endured a long illness, would not consult any physician because he hoped to live to the time prescribed, and in consequence died. (Dio Cassius.) Julian the Apostate was an adept both in astrology and magic; Maximinus and Maxentius were diviners and patrons of the art; in short, in the time of the emperors, notwithstanding frequent banishments, nothing of consequence was done without the aid of these impostors. To such a pitch had the rage for astrology risen at Rome in the days of Juvenal, that he represents his friend Umbritius, assigning as his reason for leaving the city that he was ignorant of that art, and could not gratify any heir with the prospect of his father's death:—

> "Astrorum ignoro; funus promittere patris
> Nec volo, nec possum." *Sat.* 3.

When Tarruntius, the Roman astrologer, fancied that he had discovered the day and hour when Romulus was born, as also the day on which he laid the foundation of Rome, Cicero, who ridiculed astrology, exclaimed:—"O vim maximam erroris, etiam ne urbis natalis dies, ad vim stellarum et lunæ pertinebat." The nativity of the foundation of Venice was calculated by an astrologer, who predicted therefrom its future greatness.

That astrology was cultivated in Ireland at a very early period, there can be no doubt. The druids, who were the disclosers of futurity to the monarch, were conversant with this art, and used it whenever the service of the state required it, as will be presently shown. That druidism existed in Ireland has been denied, and we are told that, "respecting druidism in Ireland, the ancient authors are wholly silent." (Edinb. Encyclop.) We shall now see whether this statement is well founded. Mr. Eugene Curry has presented me with the following translation, made by him from an Irish manuscript now in possession of the Royal Irish Academy; he declares it is one out of many which give the same information:—

"Dathi, the son of Fiacha, monarch of Erinn, who died A.D. 428, consulted his druids on the good or evil fortune of the ensuing year. His chief druid, Doghra, then retired to the Cairn on Mount Arogall, in Connaght, and when he had made his observations, he reported a favourable result to the king. The monarch called together his chiefs and leaders, and communicated the druid's prediction in a poem of ten quatrains in which the following verses occur:—

> "My druid in gifts of knowledge rich
> Delightful to me in all times
> The wonderful facts he would relate to me
> He said to me, he of the unblemished colour,
> *I shall observe the stars of heaven to-night:*
> I shall disclose unto thee royal knowledge
> Until next November all that shall happen."

We have also the authority of Pomponius Mela to the same effect.

Mr. Curry has given me another translation which shows that the renowned Cuchullan, the most distinguished of the *Heroes of the Red Branch* at Emania, the ancient royal residence of the kings of Ulster, assumed the profession of arms in consequence of the prediction of a druid.

The astrologers, in order to prove the reality and lawfulness of their art, have had recourse to scripture, which they have twisted to their purpose with some ingenuity, endeavouring to compensate the weakness of their cause by the greatness of the authority. Thus the heavens are their scroll,* on which there are signs† that declare the

* Tiraboschi has evidently overlooked what Pliny says of the physician Crinus.

* Isaiah, ch. 34, v. 4. † Genesis, ch. 1, v. 14.

glory of God, and show his handywork. That the stars have an influence and take an interest in the affairs of men, they affirm is shown by the declaration that they fought in human warfare.* That astrologers are pious men and in the favour of heaven they say is proved by their having travelled from a distant land, and were led by a star to where the infant Jesus was, and were warned in a dream not to return to Herod.† (Mag-astro-mancer of Gaule, 1652.) But determined to see only what answers their purpose, they take no notice of Deut. ch. 18, v. 10, "there shall not be found among you any one that —— useth divination, or an *observer of times*, or an enchanter, &c., for all these things are an abomination unto the Lord."

At what time astrology was introduced into medicine it is now impossible to determine. According to Pliny, it was first employed in practice at Rome by Crinus (A.D. 57), who, by his despicable stratagems, was enabled to accumulate nearly 20,000,000 sesterces. Hippocrates believed that the stars exert an influence in the production of diseases: he says that the physician should observe the rising and setting of the heavenly bodies, particularly the Pleiades, Arcturus, and the dog-star, because these periods are critical to the sick; and death, recovery, or some considerable change will happen on them. He conceived that without astrology no one can be a good physician. Galen attributes more to the moon than Hippocrates does: he believes that the critical days correspond with the different phases of that satellite. According to Sir Christopher Heydon, a man of great learning and an astrologer (1603), the scope of astrology is extensive, and its utility great: he defines it to be "that arte which teacheth, by the motions, configurations, and influence of the signes, starres, and celestiall planets, to prognosticate of the naturall effects, and mutations to come." It is divided (he says) into speculative or theoretic, and judicial or practical: the latter again into general and particular: the first considers the state of the world by eclipses, comets, and revolutions: it teaches to judge of health, plagues, death, mutations of the air, plenty, dearth, war, peace, &c.: the second treats of private fortune, and state of every singular man. Astrology prescribes rules when to purge, vomit, or bleed, and in what quantity. The astrologer shall often control the physician, as by foretelling when a phlegmatic man shall fall into a sharp and choleric sickness. The moon is the cause of critical diseases in sickness; yet by her configuration with other stars, other critical mutations may happen, which a physician, if unskilled in astrology, will not attend to, and will administer medicines at these improper periods. "Chronical diseases follow the course of the sun; but sharper diseases follow the course of the moon." The stars are "God's highest instruments in the administration of nature." (Defence of Judiciall Astrologie, 1603).

With such pretensions, it is no wonder that this art became identified in the public mind with the treatment of disease. Such was the confidence reposed in a knowledge of the influence of conjunctions and opposition of planets that the astrologer, who was merely such, and not of the medical profession, constantly attended at the bedside of the sick, along with the regular physician, and even practised minor physic and surgery on his own account independently of that functionary. Many of the iatro-astrologers acquired considerable fortunes, thereby proving the great utility of their art——to themselves. Many acquired high character as well as wealth; Girolamo Manfredi, a celebrated astrologer and physician, is said by Garzoni to have recovered several that were despaired of and dying. He also predicted to many the vicissitudes of their whole lives. Antonio Torquato Ferrarese, another of this class, beside performing great cures by his art, wrote a prophecy concerning the ruin of Europe, in which he predicted the events of the succeeding sixty years (1480 to 1540). Nicolo di Paganica, a dominican, astrologer, and physician, was so unerringly instructed by the stars that in his time neither murderer, thief, nor malefactor could escape from his judgments: he discovered and unveiled many poisoners in France, and made a new calculation of the fixed stars. (Simon di Phares.)

To such an extraordinary degree of public favour did this delusive art attain, and so wide was the spread of its contagion, that it was cultivated by persons celebrated for learning and accomplishments, and professorships began to be founded in the universities of Europe. Tommaso da Pizzano took his degree in medicine in the University of Bologna about the middle of the twelfth century, and afterwards became professor of astrology in the same university. He was astrologer to Charles the Wise, having declined the overtures of the King of Hungary; his pension was equal to 700 livres, with many other advantages, and the title of councillor. He was a man of learning and science, yet died in poverty a few years after his royal master. (Tiraboschi.)

Cecco d'Ascoli was physician to Pope John XXII. Such was his reputation as a philosopher, physician, and astrologer, that he was invited by the authorities of several cities to settle amongst them. He held the chair of astrology and philosophy for three years in the University of Bologna, and afterwards was appointed astrologer and physician to the court of Charles Duke of Calabria. Being importuned by the mother of the duke to erect the horoscope of herself and daughter, he at last consented, and predicted that both would abandon themselves to dissoluteness. This gave opportunity to his enemies to ruin him; some of his astrological opinions were pronounced heretical, and he was burnt at the stake in 1327, aged 70. (Tiraboschi.) He was a poet; his Acerba passed through nineteen editions.

The influence of astrologers on public opinion continually increased during three centuries from this time: their predictions occasionally produced remarkable effects and no small commotion. John Stoflerus, a famous astrologer, and as Mangetus says, a man of great learning, born in Suabia, 1452, foretold that there would be a great deluge in the year 1524, and thus diffused an universal terror throughout Europe. Princes, men of learning, and the common people were alike struck with dread of the calamity, especially as some of the most eminent astronomers agreed in the prediction. Those who lived near the sea or adjoining certain rivers left their habitations and sold their properties at great loss. The terror of all ranks of society, when the destiny of mankind was supposed to be near the period of its fulfilment, is incredible; the contrivances by which men endeavoured to escape a supposed dispensation of Providence were numerous; a second Noah built himself an ark; boats were at any price; and those who could contrive nothing gave themselves up to despair. There was so great a terror in France (says Bayle) that many people were like to go distracted. The great conjunction of Saturn, Mars, and Jupiter happened in the sign Pisces in the dreaded year when all the astrologers of Europe foretold this universal deluge; yet (says Bodin) God has promised that there shall be no deluge for the time to come. Gassendus adds that numbers of persons betook themselves to mountains, or ships at sea; yet that very February, when the conjunction took place and the world was to be destroyed, happened to be a remarkably dry month.

This was the second grand alarm which mankind had experienced since the deluge, relative to the destruction of the world. About the close of the tenth century and beginning of the eleventh, an opinion spread with rapidity over Europe, that the thousand years mentioned by St. John (Revelations xx. 2, 5) were accomplished, and that the end of the world was at hand. A general consternation seized mankind: many relinquished their possessions, and abandoning their friends and families hurried with precipitation to the Holy Land, where they imagined that Christ would quickly appear to judge the world. This belief was so universal, and so strong, that it mingled itself with civil transactions. Many charters in the latter part of the tenth century begin in this manner, "appropin quante mundi termino, &c.," "as the end of the world is

* Judges, ch. 5, v. 20. † St. Matthew, ch. 2, v. 2, 12.

now at hand, and by various judgments the signs of its approach are now manifest, &c." (Robertson.) An army marching under the Emperor Otho I., was so terrified by an eclipse of the sun, which it conceived to announce this consummation, that it dispersed hastily on all sides. (Hallam.)

Torquato, a celebrated astrologer, of the fifteenth century, predicted to Mathias, King of Hungary, the total ruin of the Ottoman empire after a certain time, which caused the Hungarians to engage in a war that ruined them. In times long after, Buckingham's conspiracy against Charles II. was caused by the prediction of an astrologer, that the duke should be king.

In the sixteenth century, astrology was almost universally studied, more or less, by persons of the highest rank, and even by the clergy, which was the more surprising as its tendency was to destroy the principle of free agency, to render human beings the creatures of necessity, and to place them under the dominion of the stars rather than of the Creator of these bodies. About this time, Michael Stifelius, a Lutheran clergyman, "persuaded his hearers that the end of the world would happen October 3rd, at ten in the morning. A great number of country people were so infatuated with this notion, that they neglected their work, and spent their substance. The day being come, Stifelius got into the pulpit and exhorted his hearers to be ready, for that the moment was at hand in which they were to ascend into Heaven, with the same clothes they had on." The hour passed, but nothing appeared of what they expected; when, suddenly, a storm arose, which, however, lasted only for a short time, and the sky cleared. Upon this the congregation dragged their minister out of the pulpit, bound him, accused him of being an impostor, and insisted on some reparation being made them. (Bayle.)

Philip Nicolai, Bayle informs us, said that the end of the world would be in 1670. Osiander assigned the year 1689; another named 1700. The golden age was announced to begin in the year 1624: I believe few will doubt that it has not yet arrived.

Although not as a votary of astrology, but in the character of its most devoted antagonist, the eccentric Sylvius, one of the most celebrated physicians of the sixteenth century, deserves a passing notice. He gave lectures at Paris, and had many pupils. The terms of his lectures were five pence a month, the payment of which he enforced with rigour. He was avaricious, and so extremely penurious that he allowed nothing to his servants but bread, and dispensed with fire during the winter, keeping himself warm by carrying a log of wood up and down stairs from the kitchen to the attic. A ludicrous epitaph was written for him.

"Sylvius hic situs est, gratis qui nil dedit unquam
Mortuus et gratis quod legis ista, dolet."

Here lieth Sylvius in his grave
Who when alive nought gratis gave;
And even grumbles when he's dead,
That you these verses gratis read.

Bayle informs us that at this time it was the custom to publish prophetic almanacks. Sylvius frequently altered the predictions to their opposites, and claimed, at the end of the year, to have been a more truth-telling astrologer than the compiler.

Astrological almanacks were common in these days, and physicians made use of them in their practice. In the middle of the sixteenth century, an astrological almanack was published by one Leonard Digges, in which the days proper for bleeding and taking physic were laid down; and the same course was observed by several of his successors. In the old German almanacks, the figure of a man was given with marks representing lancet punctures indicating the days and parts of the body when and where venesection might be performed. A physician named Servetus, or Villanovanus, a Spaniard, born in 1601, a lecturer on astrology to crowded audiences, projected an almanack which was to outdo all others in importance to mankind; it was to show how all manner of diseases, bodily and spiritual, might be healed by the influence of the stars. But as he announced one day to his audience that there would be an occultation of Mars by the moon, and that this phenomenon presaged a general conflagration, the death of potentates, the ruin of the church, and plague, pestilence, and famine throughout Christendom, the Faculty of Medicine cited him before the University of Paris; the result was, that he was forbidden to utter any more predictions, and his projected almanack was absolutely prohibited. This man having attacked Calvin's doctrine of predestination, Calvin became his bitter enemy, and denounced him to the Inquisition. Servetus was condemned to the stake, where having arrived in due course, he fell on the ground uttering the most agonizing yells. Being chained to the stake, a heap of straw, containing a large quantity of sulphur, was placed on his head, and over this his book was suspended. The pile was lighted, the flames rose, one piercing scream of mortal agony was heard, and all was over. (Taylor, Romantic Biography.)

The celebrated Nostradamus was astrologer to Henry II. of France, to his widow Catherine de Medici, and to her son Charles IX., whose physician he also was. He published an astrological almanack which was much relied on amongst the medical tribe; in one of these he predicted the murder of the Duke of Guise, which accordingly took place in the same year (1588). He was equally lucky in some other predictions which added much to his reputation. He had a predilection for writing in verse; his subjects were chiefly prophecies; but his poems, although frequently reprinted, are pronounced by some to have had very slender pretensions to excellence. He studied medicine and botany with great effect, and is said to have invented a medicine which did wonders in the plague.

One great cause of the unbounded influence which astrologers possessed over the minds of men was the occasional fulfilment of their predictions: many remarkable instances of this kind are recorded in the page of history. It was in vain that their prognostications so generally turned out to be fallacious; there was nothing surprising in that; their falsity was forgotten or not noticed: the artist not the art was to blame. One case of fulfilment conferred more character on their pretensions than was lost by a thousand failures. I have occasionally amused myself with noting some of the most remarkable of these successful predictions, and shall remind the reader of a few of them.

Nigidius Figulus was a philosopher and astrologer of ancient Rome, the friend of Cicero, and one of the most learned men of his day "in omnium bonarum artium disciplinis egregius." (Gellius.) Nigidius meeting Octavius, a senator, asked why he came so late to the senate? Octavius replied that his wife had been delivered of a son. Nigidius immediately prophesied the empire to the newly born infant. (Dio Lib. 56.) That infant was afterwards the Emperor Augustus. Pyrrhus, King of Epirus, was told by an astrologer that the sight of a wolf fighting with a bull would be fatal to him. On entering Argos as a conqueror, he unfortunately saw the representation of a brazen wolf and bull in combat, and at the same instant was killed by the fall of a tile on his head from the top of a house. (Plutarch.) Hippocrates by astrology foretold the plague of Illyria. (Pliny.) The Emperor Adrian, Spartianus affirms, was so skilled in astrology that at the beginning of each year he foretold all the events that were to happen to him, and even the period of his own death, and died according to promise. Ficinus declared of Leo X., when a child, that his nativity promised the highest authority in the church. Pope Paul III. (1534), well versed in the science of the stars, forewarned his son of the very day on which he should be killed. The day of the death of Don John of Austria was foretold by an astrologer. Henry II. of France was warned by the astrologer Gauricus to beware of tilting in his 41st year. In that year the king was killed by a lance. The Bishop of Vienna assured Don Frederick, on the authority of the stars, at a time when nothing was so improbable, that he should be King of Naples; he was so in twenty years

after. The same bishop truly foretold the defeat of Charles Duke of Burgundy. Picus Mirandola, the most strenuous opponent of astrology, was sentenced by the astrologers his enemies to die at the age of 33: he died at the time appointed.

Dio Cassius says that Vitellius, by an edict, ordered the astrologers to quit Italy against a certain day; they in return named a day for his death, and accordingly before the arrival of that day he died. The same happened to Domitian, who, having banished the astrologers, they retaliated by prognosticating his untimely death, which he received from the hand of an assassin. The Duke of Biron, Marshal of Henry IV. of France, laid his own horoscope before the astrologer La Brasse, as that of another person, in order to deprive him of all clue founded on probability. The astrologer predicted that the person to whom it belonged would lose his head on the scaffold, and that proved to be the fate of the unfortunate marshal. Nostradamus predicted the murder of the Duke of Guise, which happened in the same year.

Marco da Genova foretold the victory of Charles VI. over the Flemings, in 1382, and the death of Edward III. of England, in 1377. (Simon di Phares.) An astrologer having foretold that the Duke of Beaufort would escape out of prison on the next Whitsunday, the duke was secured with tenfold precautions: but he escaped on the day named. Bruce, the astrologer, foretold the death of Prince Henry, son of James I., and that the Earl of Salisbury would not live to witness it: both predictions proved true. (Jesse.) Lady Eleanor Davies foretold that William, the third Earl of Pembroke, would not see his fiftieth anniversary: he died the day before. (Countess of Blessington.) John Baptist Morin, a physician and astrologer, being consulted by Cardinal Richelieu as to the probable period of the death of Gustavus Adolphus, calculated his nativity, and ascertained it within a few days of the time when it really took place. He foretold Richelieu's own death within ten hours of the true time; he foretold that Louis XIII. would be seized with a dangerous disease at Lyons, but that he would ultimately recover: this accordingly happened. Other astrologers who had pronounced the disease mortal were sent to the galleys. He calculated the events of the year 1617, and foresaw that the bishop of Boulogne was threatened with imprisonment: the bishop ridiculed the prediction, but soon after found himself incarcerated. Muley Aben Hassan, Moorish King of Granada, had a son named Mahomet Abdalla, at whose birth it was foretold by the astrologers that he should reign, but that during his life the downfal of the Moorish kingdom of Granada should take place: and so it did (1492). Erasmus, who ridiculed astrology, jesting with a friend, predicted that the friend should be married to a rich but ill-tempered wife, and that they should be separated, both of which occurrences took place.

An astrologer had foretold to Pope Alexander VI., who died in 1503, that so long as he carried about him the consecrated host, he would be proof against assassination by poison or dagger, and no longer. It was therefore the custom of the pope to wear a gold chain round his neck, from which hung a medallion, in which the host was contained. On a particular occasion, when he was on his way to his villa, where he had invited some friends to supper, three of whom he intended that night to poison, he discovered that he had forgotten his medallion. He immediately sent for it to the vatican, but being thirsty he sent forward to his villa for some wine. By mistake, singularly brought about, the poisoned wine was brought him, and the prediction of the astrologer was fulfilled. That pope who never before did justice to man, received retributive justice from his own hand: in a few days he died.

The Chinese emperor, Iin-Tsong, A.D. 1384, was an astrologer. "Having spent a whole night observing the stars, and perceiving some change in the heavens, he sent for two of his Ko-laus, to whom he said, 'my life is at an end.' From that time he languished, and soon died." (Du Halde, Descrip. of China.)

It is of little use to proceed with further instances: the cases of Ascletarion eaten by dogs; of Caracalla assassinated at the suggestion of Macrinus; of Henry IV. of France; of Henry IV. of England; of Lady Eleanor Davies, who truly predicted the birth and death in one day of a son of Charles I.; of Dryden and his son Charles; and many such will, no doubt, occur to the readers of history.

Thus did chance befriend the astrologers: but frequently the event was brought about by the prophecy. Even when the prediction was falsified by the event, accident sometimes saved the reputation of the astrologer. Thus a Silesian nobleman, having consulted the astrologers as to the manner of his death, was told by one that he should die of fever; by another, that he should be killed by a fall; and by a third, that water would be fatal to him. They all proved right. The nobleman caught fever; in his delirium he threw himself out of a window, and fell into the stream beneath, where he was drowned.

An astrologer foretold to Monsieur, afterwards Louis XVIII., that the son of Louis XVI. would die after the termination of his father's reign, yet that his immediate successor would not be Monsieur, but another. (Memoirs by Louis XVIII.) This was, perhaps, no more than the foresight of a sagacious politician; and no doubt many predictions of astrologers were of the same kind.

Astrological predictions were sometimes so cautiously dated that their failure would not be discovered until death had removed the prophet beyond the reach of disgrace. Of these there are many instances. Torella, who lived about the period of the first appearance of the venereal disease, attributed that calamity to a malignant conjunction of certain planets; but Petrus Maynardus, a Veronese astrologer-physician, calculated, on astrological principles, that this disease would disappear from the world in 1584—a flattering tale which unfortunately has not been realized.

In the middle and later ages, crowned heads attached professed astrologers to their respective courts; the persons so selected were generally physicians, but when they were not such, and even frequently when they were, there was a court physician or perhaps two.

When the caliphs ventured to emerge from the ignorance in which, after the example of the holy prophet, it was deemed a virtue to remain, they began to cultivate arts and sciences. Abou-Giaffar-Almansor promoted the study of poetry, mathematics, and philosophy; and, notwithstanding the denunciations of Mahomet against astrology, he took into his court a state astrologer and two state physicians.

William de Perepond was not only astrologer to Henry III. of England, but his chief adviser. Sir Michael Scott, a Scotch gentleman, possessed of extensive learning, was astrologer to Frederick II., emperor of Germany. He was believed to be so profoundly versed in magic, that it was deemed dangerous to open one of his books lest some foul fiend should forthwith intrude his unwelcome company. On his death, it was deemed the most prudent course to get a quiet riddance of his body and books together, and accordingly both were deposited in the same grave. Boccacio calls him the great master of necromancy. He was also a chiromancer and an alchemist. Dante, with his characteristic charity, has placed him in hell along with Bonatti, another astrologer, and certain popes, cardinals, and legates:—

> "Quell' altro, che ne' fianchi è così poco,
> Michele Scotto fu, che veramente
> Delle magiche frode seppe il gioco.
> Vede Guido Bonatti. (*Inferno.*)

He represents the two astrologers with their faces twisted behind their backs—a position which Rosetti explains by their having during life seen too much *before* them. Bonatti, previously to his death, as a pious reparation of past errors, had joined a religious fraternity called l'Ordine de'Minori, who were the greatest enemies to astrology. He was for a time astrologer to Frederick II. of Germany, and died about the end of the thirteenth century. By a conjunction of planets, as he says, he discovered a con-

spiracy against his royal master, which really existed, and boasts of several fulfilled predictions: in others he was unfortunate. Amongst many ridiculous stories, he is represented to have made a brazen statue which returned prophetic answers. He left behind him a complete treatise on astrology, in which he is supposed to have been at first a sincere believer.

Henry Cornelius Agrippa, born at Cologne in 1486, possessed talents of a high order, which, along with uncommon acquirements in languages and science, qualified him to act in almost any capacity. His course of studies, preparative to his obtaining the degree of Doctor of Medicine, directed his attention to alchemy, in which vain art he soon acquired a reputation that has never been surpassed. So great an object was it considered to secure the services of one who could so compendiously accumulate wealth that many of the crowned heads of Europe made him splendid offers of settlement at their courts. Beside alchemy, he professed astrology, geomancy, and the calculation of nativities; it was pretty generally affirmed that he also practised magic, using as his familiar a demon in the form of a black dog, by which he was always attended. At length, in 1526, he engaged as physician in the service of Louisa of Savoy, at the court of Lyons, but was in a short time dismissed for indignantly refusing to gratify her with a prediction on the result of a war in which her son Francis I. had engaged. Talents like his secured him patronage, and he was soon besieged with proposals, amongst the rest those of Henry VIII., to become Astrologer Royal; but he gave the preference to the friendship of Margaret of Austria, which at length he lost by publishing some indiscreet satires on the times. In these he did not spare the clergy; and their retaliation caused him to suffer extreme vicissitudes of fortune during the remainder of a life which terminated in the greatest poverty at the age of 49. At different periods of his career he fulfilled public duties, varying much in their nature. At one time he served in the wars of Italy, as an officer, under Maximilian I., and for his courage and conduct was rewarded with the honour of knighthood; he afterwards became a lecturer on theology; was secretary to Maximilian, and afterwards historiographer to the Emperor Charles V.; beside being doctor of laws and of medicine, he filled many honourable situations. That a mind elevated by diversified learning and high rank should, for private advantage, descend to the lowest fraud and imposture, practised on the ignorant and unwary, to the disgrace of science and the delusion of mankind, is an occurrence rare in the history of letters. His imprudence often caused him great misery; a capricious temper repulsed his friends; a restless disposition obstructed the steady fulfilment of his duties; and lamentable to say, his redeeming quality, a manly love of truth which appeared in his writings, although not in his actions, made enemies of those who should most have valued such a quality. His life was a succession of vicissitudes: at one time he was exalted to the pinnacle of fortune, at another abased by poverty and disgrace; this year pampered in a palace, the next languishing in a prison. Such has often been the fate of genius when unrestrained by prudence and moderation. His reliance on his proper province, that of a physician, seems to have been weak enough. In his book on the "Vanity of the Sciences," written in after life, he declares that the physician's prescription is more dangerous than the disease. In the same work, he pronounces geomancy, divination, and astrology, all of which he had practised, to be superstitious, false, and lying; he also includes magic, which he is said to have been skilled in. The Emperor Charles V. of Germany imprisoned him for suggesting to him a process for finding treasure by means of magic. A vulgar notion prevailed that he paid his debts in magical money, which, appearing good, soon turned into dross. (Gaule.) It was also reported amongst other absurd stories that he exhibited to the Earl of Surrey a magic mirror in which the noble poet's lady love, the fair Geraldine, was rendered visible, at that moment reading one of the earl's sonnets.

(To be continued.)

CASE OF TRAUMATIC TETANUS.

By Edmund Sharkey, A.B., M.B., T.C.D.,
Medical Attendant of Moore and Creagh Dispensary.

The following case, which has occurred within the last few days, seems to form an appropriate appendage to that detailed by Mr. Butcher in the Medical Press of July 30. It is strongly distinguished from it by its less degree of intensity, and the comparatively painless passage of the little sufferer to the grave:—

July 26, 1851. Thomas Burke, a child of six years old, was this day brought into town to me, having sustained a compound fracture of the humerus by a fall from a donkey. On examination, I found the lower end of the humerus broken off, just at its junction with the condyles, with its fractured extremity protruded two inches through a ragged wound. There was no wound of the artery. It was necessary, in order to its reduction, to incise the integuments to some extent. A bandage and splints were loosely applied, and he was sent home, a distance of about a mile from town. Cold water was directed to be applied.

31st. No untoward symptom appeared up to this time. The little patient slept well; his bowels acted regularly; there was no evidence of fever. To-day, however, my attention was attracted by the almost gangrenous fœtor of the ichorous discharge from the wound, which does not present any appearance of granulation; also by spasms of the arm, so little remarkable, however, as scarcely to be distinguishable from the voluntary contractions which might have occurred in so young a patient wincing during the operation of dressing. They were, however, more frequent, and more perseveringly performed notwithstanding my remonstrances, than was to be expected from a little patient who had hitherto been most enduring and tractable.

August 1st. On receiving an account this morning "that he could not open his mouth, and was very low," I visited him, and found him affected with trismus and the same spasms of the arm, but very little else to cause the disease of tetanus to be recognized—no extraordinary rigidity of abdominal muscles; no opisthotonos; the bowels not constipated; no distress apparent in countenance; his abdomen slightly tympanitic. I ordered calomel and warm baths.

2nd. On going to visit him to-day, I was informed that he had died without suffering: his bowels had been previously moved.

This case presents a remarkable contrast to Mr. Butcher's, in which, from a wound, leaving scarcely a visible trace, there resulted such an amount of agonizing convulsions; while, in this, after a wound of such a formidable nature, a much milder form of disease proceeded nevertheless to a fatal termination. I had thought of using chloroform, but did not think it called for by the amount of nervous derangement present.

Ballinasloe, August 4, 1851.

Poisoning with Muriate of Baryta.—A student of medicine, who supposed that he swallowed three teaspoonfuls of sulphate of magnesia, was seized with tormina and vomiting; the pulse was weak and irregular; the tongue natural. Dr. C. Wolf, who attended the case, at first supposed it to be one of summer cholera, excited by the purgative; but as in half an hour more he found his patient with ice-cold extremities; pulse 65, irregular and feeble; hands and feet powerless; paralysis of the left eyelid; the voice weak, and incessant griping. He analyzed what remained of the so-called sulphate of magnesia, and found it to be muriate of baryta. The patient took only some sulphuric acid and castor oil, by which the griping was soon removed, but there came on retention of urine requiring the catheter. The muscular powerlessness soon disappeared, and in three days the patient was quite well. He had taken altogether three drachms of the salt. Dr. Wolf detected the chloride of barium in the evacuations by incinerating them.

CASES OF AMPUTATION:

1st. Below the Knee, subsequently to the Removal of the Foot at the Tibio-Tarsal Articulation; and 2nd, at the Shoulder, during Spreading Gangrene, consequent on Disease of the Elbow-joint.

THE APPLICATION OF A NEW SAW IN BOTH. WITH OBSERVATIONS.

By RICHARD G. H. BUTCHER, F.R.C.S.I.,
Examiner on Anatomy and Physiology in the Royal College of Surgeons of Ireland;
Surgeon to Mercer's Hospital,
&c. &c. &c.

WILLIAM FLYNN, aged 25, a labourer, was admitted into Mercer's Hospital, May 15, 1851. In November, 1849, he had suffered from a severe injury of the foot, which occurred in the following manner:—

Having been employed to mind a kiln in which limestone was being burned, he fell asleep at the edge of the crater, when his left leg slipped over the margin on the heated stones; he was quickly awakened to a consciousness of what had occurred, by a sense of severe pain, and, on examination, he found that his foot was very deeply burned, the four inner toes being almost charred, while the little one, together with the tarsus, escaped uninjured. The integuments were also destroyed to the extent of three inches vertically, and two inches transversely on the anterior aspect of the lower part of the middle third of the leg; the thigh suffered slightly on the outer side in its inferior third. As the result of the injury sustained, acute inflammation rapidly followed, particularly in the leg and foot, but of a milder character in the thigh which soon healed, while the leg continued sore for two months before cicatrization was complete, and at the end of three months the toes were cast off from their connexion with the metatarsal bones by ulceration. The wound resulting from this ulcerative process entailed long confinement, and the cicatrix consequent upon its healing was hard, unyielding, and sensitive to the touch in the outer half, while that on the inner half, corresponding to where the great toe and the toe next it were attached, continued painful, inflamed, and discharging a thin sanious fluid. In this condition he continued to move about with the aid of crutches, resting his weight partly upon the heel of the affected limb. In October, 1850, he was admitted into St. Vincent's Hospital, under the care of Dr. Bellingham, who, early in December, performed amputation at the ankle-joint, in the manner recommended by Mr. Syme. Two months after having been dismissed cured from St. Vincent's Hospital, he presented himself for admission at Mercer's Hospital.

He then stated that, from the time of his dismissal he was never able to lean the weight of his body on the stump, though assisted with crutches; that he frequently endeavoured to habituate the part to gentle pressure, but whenever he attempted to do so, inflammation and increased tenderness of the cicatrix were instantly aroused, which forced him to desist. Not only did the cicatrix become painful, but it ulcerated externally for about an inch. At the same time the cicatrix resulting from the burn in the lower third of the leg again broke out, and assumed the characters of a very irritable form of ulcer, accompanied by excessive pain. From the patient's constantly hopping about on crutches, with the ulcerated leg dependent, it became swollen and œdematous, measuring in circumference above the ankle nearly twice the size of the sound limb. Together with the increase of bulk, the colour was of a dark red hue from extreme engorgement of the minutest vessels. Coexisting with this laboured circulation, there was a deep heavy pain, particularly elicited on the least pressure over the stump, and if the pressure was made over the inner side of the cushion, pain of a very acute character instantly darted up the limb, which as instantly subsided on removing the hand, but could at once be reproduced by the same manœuvre. This test evidently proved that the nerve was involved and productive of it.

The patient came into hospital, and placed himself under my care, with the determination of having his leg removed below the knee, and urged as his reasons the pain he had endured and was suffering, the total uselessness of the limb for progression when he was dismissed from St. Vincent's Hospital with the stump healed, and it being an impediment to his following any mode of business for his support.

In consultation with my colleagues, Mr. Tagert, Dr. Jameson, and Dr. Bevan, they at once acquiesced in my proposal of amputating immediately below the knee. A few days were allowed to elapse before the operation, in order to facilitate the emptying of the overloaded vessels and the infiltrated tissues of the limb, a result which was readily brought about by position, judicious bandaging, &c.

May 20th. The removal of the limb having been decided on this morning, I preferred the method by the double flap operation, and proceeded to execute it in the following manner, preserving about four inches of the leg. The sound leg being secured to the table, standing on the right side of the patient I applied the anterior part of the blade of a long catlin half an inch behind the external edge of the fibula, carrying the instrument downwards, parallel with the bone, for three quarters of an inch, and then sweeping it rapidly in a curve (the convexity downwards) across the front of the leg, until it reached the inner edge of the tibia, when it was directed upwards along its inner margin to the point opposite to where the knife was first laid on, and then, without lifting the blade, the calf was transfixed and the instrument carried quickly downwards, so as to form the posterior flap. The anterior flap, consisting merely of the integuments, was then dissected back a short way, retracted together with the posterior one and retained so by Dr. Bevan, while the amputating knife was swept round and between the bones, as in the circular operation, a little higher than the line of transfixion, thus dividing, posteriorly and in front, the muscular fibres attached to them. A linen retractor was then passed between the bones, and drawn upwards, so as carefully to protect the posterior flap, while the anterior one was dissected up a little way, in order to admit beneath it, to the very line of its osseous connexion, the blade of a fine bow saw, which was placed almost flatly at first on the tibia, and then directed somewhat backwards, so as to cut the bone in a curve (the convexity downwards) to half its depth, the remaining portion, together with the fibula, being severed by working the saw directly backwards. By this manœuvre it will at once appear that the sharp spine of the tibia was removed in the same section as the rest of the bone. Of the many advantages resulting from the application of this saw I shall speak more fully presently. The anterior tibial, the posterior tibial and peroneal arteries, were then secured; the anterior tibial vessel did not retract, as noticed by some writers, neither was there any difficulty experienced in tying it. The posterior tibial was found and secured more than two-thirds down the flap, and the peroneal ligatured in the usual place, close to the inner edge of the fibula. There not being any other vessels disposed to bleed, the patient was removed to bed, the limb supported on pillows, and the stump exposed to the air to glaze. The operation was performed while the patient was under the influence of chloroform, and its admirable effect in this case cannot be overpraised. In a minute and a half he was placed perfectly under its influence, retained so for a few seconds, and as rapidly roused from insensibility by the fumes of ammonia. The patient awoke to perfect consciousness, entirely ignorant of what had taken place, not having the slightest perception of the least degree of pain during the amputation of the limb.

In four hours after the operation I proceeded to dress the stump; reaction was fully established, and no hæmorrhage, venous or arterial, had occurred; the entire surface of the posterior flap was glazed over. The limb could not be touched or the flaps raised, without exciting the greatest torture and violent spasms of the muscles of the thigh. So violent were the patient's struggles, that had we per-

sisted, it is more than probable he would have been seized with convulsions. In this dilemma I at once decided on again putting him under the influence of chloroform. Its anæsthetic effects were as readily induced as in the morning, and then all was calm, perfect immunity from pain having been produced. I quickly proceeded to bring up the posterior flap in apposition with the anterior one, retaining it so by five points of the interrupted suture, and in the intervals applied straps of adhesive plaster; a few folds of fine linen, wet with cold water, were then laid over the face of the stump, which completed the dressings. The limb was steadied on a pillow, and motion prevented by a broad piece of linen, extending from the knee to the middle of the thigh, and secured by pins to the mattress on either side.

Ten p.m. There was slight tendency to starting and spasm in the muscles of the thigh, but he was quite free from pain. He was ordered an anodyne draught.

21st. Slept at intervals during the night, tendency to spasm having ceased almost immediately after the opiate; pulse 88; temperature of the stump a few degrees higher than natural, being moderated by the application of cold. The draught was ordered to be repeated at night.

22nd. Slept well; no pain; no startings; no secretion of pus as yet, nor oozing of fluid from the stump; cold to be still continued at intervals, the object being to permit an increase of heat beyond a few degrees; the draught to be repeated at night.

23rd. Slept all night, and quite free from pain; the only indication of not being well is the total absence of appetite; pulse quiet, 84.

24th. All tendency to startings in the limb has ceased; there is slight purulent discharge from the inner angle of the wound; I removed one strap of adhesive plaster over this point, and quickly replaced it by another; the sutures are all in position, and there is no trace of irritation about them. Having expressed a wish for food, he was allowed some light farinaceous diet.

25th. Slept the entire night without an opiate; appetite quite restored; pulse quiet; skin cool; the stump presents a most favourable appearance; the outer part of the wound being nearly healed by first intention, I removed two of the stitches corresponding to it; there was not the least blush of inflammation about either, their presence being marked only by a drop of pus following the thread as it was withdrawn; straps of adhesive plaster were applied to support the flaps in lieu of them; the dressings over the remaining portion of the wound in its two inner thirds did not require to be disturbed, there being scarcely any discharge, merely a trace of it along the course of the ligatures. The stump lies still on a pillow, supported as before, merely with its adhesive straps, and remaining sutures: these, together with a few folds of fine linen damped in cold water, were all the dressings employed.

26th. Slept all night without an opiate, not having experienced pain or uneasiness in the part; all the straps of adhesive plaster, together with the three remaining points of suture, were removed to-day; not that the latter were producing any irritation, but that they ceased to further the healing process any more; altogether the stump presents a most favourable aspect; more than the outer third is united by the first intention, and the remaining portion shows a healthy, granulating surface, not wider than three-quarters of an inch in any part between the flaps.

27th. Readjusted the adhesive straps, and placed over them along the track of the wound a strip of lint smeared with zinc ointment.

June 1st. The outer half of the wound is perfectly cicatrized, and along the remaining portion the healthy granulating line between the flaps is not more than half an inch in breadth; new skin creeping in rapidly from both sides. Could commit so great a mistake, I conceive, edges on this surface; the ligatures lie still undisturbed. just as readily consummate the blunder by trans-

6th. Progressing most favourably. I gently pulled the ligatures to-day, but each remains undetached.

12th. Wound all healed, though ligatures not [illegible]

14th. Ligatures readily came away on traction; stump quite healed.

15th. The stump is now healed throughout, is perfect in every respect, and bears any amount of pressure. When it is placed at right angles with the thigh, the cicatrix is still loose, and a free movement of the integuments permitted over the knee-joint.

I selected the operation by flaps, in this case, in preference to the circular method, not lightly or without thought. For years I have been in the habit of observing the results of each form of operation, and in my own mind, at least, accounting for untoward events, whenever they occurred. After the computation of a large number of cases, results, &c., I am firmly convinced of the superiority of the method by flaps, when effectively and efficiently executed. I am quite aware, when I make so bold an assertion as this, that it is contrary to the predilections of many senior and experienced surgeons, who have been wedded to the circular operation. Should I be considered presumptive for so startling an assertion, I willingly bear the imputation, when I can urge the powerful evidence of Mr. Liston in corroboration of my own views, one whose faithfulness is stamped in imperishable letters on every record which he has left behind. The following remarkable passages occur in the writings of this distinguished surgeon; at page 375 of his Practical Surgery, he says:—"A surgeon must take great pains, and deserves great credit, if he succeeds in making a tolerable stump, more especially when there are two bones, by any other than the mode by flaps; he may cover the bones certainly, but only by integument separated by a painful process from its connexions, and slow, therefore, in contracting new ones." And again, a little before this passage:—"The soft parts and bones not having been well proportioned, the cicatrix, if completed, is tender and liable to ulceration; the ends of the nerves, naturally bulbous when truncated, are exposed and entangled either in the scar or with the end of the bone; and the patient is thereby kept in a constant state of agony. This must be the case very often, so long as the old, round-about, tedious, painful, and imperfect operation continues to be practised. It is true that in some situations, a good operator can make a very fair and good stump by the circular method, but it is, generally speaking, attended with more suffering, and the results are not by any means so satisfactory."

Further in support of the position I maintain, I will adduce the authority of Professor Fergusson, at page 155 of his Treatise on Practical Surgery. He concludes, after making some observations on both methods, by saying:—"Any one who has had opportunities of contrasting the two modes, must have been struck with the apparent advantages in the execution of the one over the other; the facility of selecting a flap from any convenient side, the comparative ease with which it may be cut, the certainty of preserving a sufficiency of soft parts, the readiness with which the bone can be exposed for the application of the saw, are all, in my opinion, important advantages in favour of the flap operation."

I shall now take a review of the leading features of this case, and show how many of the objections urged against the flap amputation may be guarded against.

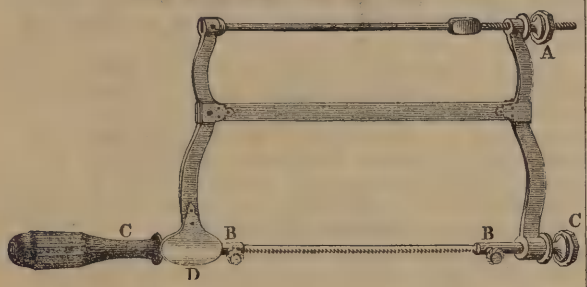
As to the position the surgeon should take, when about to perform amputation of the leg, much has been written and said, some contending for one side, while authorities equally as high have proclaimed for the other; the chief grounds upon which the conflicting opinions rest being founded on the anatomical relationship that is known to subsist between the tibia and fibula in their upper parts, the posterior margin of the latter being on a plane considerably behind the broad surface of the tibia; from which it is argued, should the knife be thrust from within, it is [illegible] to be passed between the bones; but the awkward-

stands, it is essential he should remember the surface which the bones, taken together, form pos- and over which the knife is to glide. In the case ast adopted, I preferred forming a semilunar flap in front,

an inch and a half in length, to the method recommended by Mr. Hey, of drawing the knife straight across the forepart of the leg; and, for these reasons, it meets in approximation more readily the edge of the posterior flap, and lies more evenly in connexion with it; and, above all, when the cicatrix is perfected, and the knee bent at right angles with the thigh, so as to rest in the socket of the wooden leg, the integuments are not strained or tightened. The preservation of the integuments in front then, by the anterior flap, I look upon as a most important feature, bearing on the after condition of the stump; but this of itself will not be sufficient to guard against a dragging of the cicatrix, unless the sharp spine of the tibia be sawn off. I am quite satisfied many of the cases of failure, the ulcerated stumps, &c., which have been ascribed to the weight of the posterior flap, the dragging on the cicatrix by the gastrocnemius muscle (which in reality can have no action at all, when the stump is at right angles with the thigh), may be more properly ascribed to the neglect of these two points; and the proof I would urge forcibly presents in the fact, that a like sequence not unusually occurs after the circular operation, when the sharp angle of the tibia has been allowed to remain.

In all cases I prefer standing on the right side of the patient; it leaves the left hand free, and in the most favourable position for facilitating the progressive steps of the operation, particularly in holding up the anterior flap, when the spine of the tibia is removed in the manner which I have already adverted to.

The saw which I have used in this operation, and which I most strongly recommend now, for the first time, to the profession, is a modification of the bow-saw used by cabinet-makers for cutting out fine work, when curves are to be executed. The construction of the instrument will be readily understood by the description appended to the wood-cut, in which the saw is exhibited on a very reduced scale.



The measurement of the full-sized instrument is as follows: the upright pieces are six inches high, half an inch wide, and two lines thick; the one remote from the handle is received into the transverse bar, and is moveable; the depth of the blade is three lines, with the teeth well set off from each other, and inclined forwards; the length of the blade is six inches, with the sockets included eight inches and a half; the middle bar is half an inch deep, and two lines thick, and the upper bar is rounded, with a screw at one end.*

The instrument, for amputation of the leg and thigh, I have had made of the above proportions, but it is also executed on a smaller scale for minor operations. I have also, at this moment, in the hands of the cutler a saw preserving the same proportions of blade, with a screw to make it tense, directly attached to the remote socket from the handle of the instrument; by this contrivance the upper bar, and a great proportion of the uprights, can be done away with, so as to render it more portable.

The advantages which I conceive this saw possesses over every other, are the following: from the extreme shallowness of the blade, it readily cuts in a curve, if required; and from its slender proportions it can be easily slipped under the flaps and used without bruising them, or catching in the retractor. No matter how unsteadily or unevenly the limb is supported and held by the assistant, the saw cannot be locked: the thin shallow back, the fine setting of the teeth, the mode in which they project to either side, all contribute to prevent the possibility of such an occurrence, for a perpendicular section of the blade shows it to preserve a triangular form, the base below, therefore the instrument must work freely in the groove which it has made. It cuts more evenly than any other saw, and the bones cannot be splintered by it, consequences resulting from the fineness of its setting, and the lightness of the instrument; and lastly, it cuts more rapidly than any other saw, owing to the extreme tension of the blade, produced by acting on the screw in connexion with the upper bar of the instrument; the effect being perfected in a very material manner by the mode in which the blade is riveted in a direct line with the teeth.

This saw will be found extremely useful in every instance where a saw is required, and particularly in amputation of the lower jaw; for, by relaxing the screw above, the sockets in which the blade is lodged are permitted to rotate, so that the teeth may be directed outwards, while, by unscrewing the pin marked B, the blade is readily detached, and, being sharp at the point, is easily passed behind the bone, with its edge applied to it, or at any angle required; the blade is again fastened at B, and when made tense, a few movements of the instrument will readily sever the bone from within outwards.

Again, owing to the facility it affords in cutting curves, it is peculiarly applicable for removing exostosis, cutting out the great trochanter of the femur, &c.

Every surgeon will admit and act upon the grand principle inculcated by modern surgery, to save and protect as much of the body as possible from mutilation; yet in the subject before us there are two points particularly worthy the attention of every practical surgeon; first what are the advantages obtained by the amputation at the ankle-joint, and its applicability to all classes of society? and secondly, its terminal results. I have before me at this moment a cast which I procured through the kindness of Dr. Bellingham, taken from the patient, Flynn, immediately on the parts being healed, after the operation at the ankle-joint, and before he left St. Vincent's Hospital. Nothing can be more perfect than the formation of the stump. It is a beautiful round cushion, and as it rests on a horizontal plane, the cicatrix in front is fully an inch and a half above it. From its perfect proportions it is quite apparent that an admirable covering can be obtained for the ends of the bones in this place of selection.

(To be continued.)

* A, the nut applied to the screw, which makes tense the blade; B B, the pins that secure the blade in the sockets; C C, the handle and nut, by turning which the blade is rotated to any angle; D, the rest for the index finger.

BRUCINE IN LEAD-PALSY.—As an internal remedy in lead-palsy, brucine possesses advantages over strychnine, as it is capable of being safely administered in larger doses. M. Bricheteau gives it at first in doses of two or three centigrammes (about one-third to half a grain) daily, and sometimes raises the quantity to eighty centigrammes; but this is rarely necessary. At the dose of from ten to fifteen centigrammes, it produces slight twitchings, with a creeping sensation in the limbs. When the dose is raised to twenty or twenty-five centigrammes, the twitchings become more powerful, and begin to be accompanied by stiffness of the limbs, which are put in a state of forced extension. When the patients are still, the convulsive movements are but slight: but if they move in bed, the twitchings and tetanic symptoms appear. When they walk, their limbs become stiff, and they fall forward, if not supported. These symptoms are not accompanied by disturbance of the intellect, nor by headache. In a case lately under the care of M. Bricheteau, of paralysis of the extensors of the thumbs and fingers, the good effects of the treatment were complete. The paralysis was complete; but, in a month, the patient was able to raise the thumbs, and ultimately made a perfect recovery.—*Bulletin de Thérap.*

NEW YORK PATHOLOGICAL SOCIETY.

ICHTHYOSIS CORNEA, OR BONY TUMOUR OF THE LOWER LIP.

By Lewis A. Sayre, M.D.

Captain Comstock, aged 56, robust, and good constitution, discovered, about six years since, a small scale upon his lower lip, which was without pain easily torn off, without bleeding, but soon returned, and had the appearance of a hard wart. It was removed by Dr. Marsh of Albany, about four years since, by an incision, which soon healed kindly; but in a few months returned in the same place. Caustics and arsenical washes were applied, but it grew more rapidly, in a conical form, but did not extend over so large a base. To prevent the deformity, he constantly clipped off the end with the scissors.

At present it is about half an inch long, the growth of nearly three months, and about half an inch in circumference, growing from the middle of the prostomial edge of the lower lip. I removed it by a V incision through the integuments only, not dividing through the mucous membrane, and thus avoided the coronary artery. The wound was brought together by three stitches, and dressed in the usual way. All healed kindly by first intention, in five days.

Boyer says that these horny growths are formed of a substance similar to the nails, and are secreted in the inner surface of the sebaceous follicles; first soft, then hard and tough, and may grow to several inches in extent. During the early period of their formation, and when they are of small size, they are surrounded with a membrane which makes them appear encysted; but as they increase in length, the membrane only envelops their base. They never extend more deeply than the follicles, into which they appear to be set. The cyst or cavity in which they are planted is sometimes the seat of chronic inflammation, which occasionally ends in ulceration, when the horn falls off, and thus effects a spontaneous cure.

CASE OF OSSIFICATION OF THE RETINA.

Dr. Isaacs exhibited a specimen of ossification of the retina, taken from a dissecting-room subject, from which no history could be obtained. Upon this specimen, Dr. Isaacs remarked:—Specimens similar to the one here exhibited are rarely met with, and, according to authors, very seldom, except in eyes which have been more or less disorganized by acute inflammation for a long time previously to death. In an eye, dissected by Magendie, the retina was converted into a white, firm, fibrous membrane; *on the outside* of the retina was an osseous stratum, from one-fourth to three-fourths of a line in thickness. The choroid adhered to the external surface of this bony layer. This would appear to have been an ossification of the membrana Jacobi. Meckel considers this membrane as the seat of the ossifications found between the choroid and retina, and as analogous in its character to a serous membrane.

Cases of ossification of the retina are recorded by Scarpa, Panizza, and Juenken of Berlin, and a specimen preserved in St. Bartholomew's Hospital is referred to by Lawrence. Haller, in his Opuscula Pathologica, describes an eye which he dissected, "the cornea of which was opaque, and the globe hard; within the choroid, and concentric with that tunic, in place of the retina, there was a hollow, osseous, or rather stony hemisphere, for no bony fibres were discernible to which the choroid adhered, as it usually does to the retina. That this sort of cup was the retina, was further proved by the circumstance of its being perforated by an accurately round opening, at the entrance of the optic nerve. No proper vitreous body was found in this osseous cavity, but a kind of nerve, that is, a white cylinder, which, entering through the foramen of the bony cup, passed along its axis, and adhered in front to a confused mass of bone, which was probably the degenerated crystalline. In this same mass, the iris, ciliary processes, and cornea, were firmly consolidated."

Ulcers.—In chronic ulcers, resulting from scrofulous diathesis, Dr. Beneke says, give phosphate of lime, in doses of from eight to twenty grains per diem. It should be ordered to be taken with the breakfast, dinner, and supper, so as to be thoroughly mixed with the food. These cases are accompanied always by a want of the proper cell-growth, which the phosphate is said to increase in a remarkable manner. The phosphate, nevertheless, cannot be said really to cure the scrofulous dyscrasia, but we shall certainly promote the cure in the most efficient manner by its administration.

HOSPITAL REPORTS.

ST. BARTHOLOMEW'S.

Poisoned Pustule of the Lip.

(Under the care of Mr. Stanley and Mr. Lloyd.)

If in this country very sad cases of glanders, dissection wounds, &c., are but too frequently met with, as resulting from the absorption of some morbid poison, we seem on the other hand, to be free from the terrible disorder, called by our continental brethren, "carbon, or pustule maligne," which is likewise supposed to owe its origin to some infectious animal matter. But if this disease be rare, we now and then see another which bears a strong analogy to it—namely, a pustule developed in some part of the face, mostly the lip, the intense inflammation of which is excited by a poison not altogether perhaps belonging to the animal kingdom, but exercising (whether it be a mineral or a vegetable production) a severe irritation on the spot where it happens to become deposited.

The previous condition of the patient has doubtless some influence on the rapid development of symptoms; but there must certainly be a great morbific power in the particles which give rise to the violent local manifestations, and the typhoid character of the accompanying fever. Examples of such an affection, as involving the lip, have lately been noticed at St. Bartholomew's Hospital, and though the cases at first looked very much like instances of malignant pustule, it was evident that all the characters of the latter disease were not present.

It was thus tolerably easy to make out what it was not, but a much more difficult task was to assign to the cases their proper place in the nosological classification. This was not, however, the principal point; a more interesting one, especially as the cases followed each other rapidly, was to determine which was the most advisable line of treatment. From the following particulars it will probably become clear that support, and the free use of the scalpel on the inflamed part, is the course most likely to yield favourable results. We proceed to give a few details of the cases.

Case 1.—Henry R——, aged 18, a lad of average stature and pale countenance, was admitted into Darker ward, under the care of Mr. Stanley, February 25, 1851. The upper lip on the right side of his face is much swollen, its surface of a livid redness, exhibiting a few scattered points, whence some purulent-looking matter exudes. The patient complains of a dull, aching pain in the right side of his face, though in tolerable health otherwise. Skin warm and moist; tongue humid, covered with a brown fur in the centre, and papillæ prominent; pulse 80, soft, and very compressible.

His employment is that of a turner. Eight days ago he noticed a pimple on his upper lip, about the situation of the junction of the skin with the mucous membrane. On the same evening he scratched off the head of this pimple, and fancies that some of the rosewood dust came in contact with his lip. From the time of its commencement, the sore has gradually been getting worse, with a great deal of throbbing pain, preventing the patient from having any rest at night. Breathing tranquil.

The house-surgeon made a crucial incision into the swollen lip and another longitudinal one at its lower part. Beef-tea, wine and bark were prescribed, and a poultice applied to the inflamed spot. On the next day the patient was doing very well; there was more discharge from the lip, and the inflammation and pain had diminished. The same treatment was continued. From this time the lip improved, and the patient was discharged in a few days quite well.

Case 2.—James C——, aged 36, was admitted into Darker ward, February 3, 1851, under the care of Mr. Stanley. Both lips were much swollen, and covered at their edges with pustules; the skin and cellular tissue were red, hard, tense, and œdematous, and appeared in a state of phlegmonous inflammation. This was more extensive round the upper than the lower lip. The whole of the

right cheek above the mouth was swollen, and the right eyelid puffy; countenance not distressed; skin warm and soft; tongue furred, but moist; pulse 144, sharp, and compressible; complains of thirst, and loss of appetite; bowels not open for two days.

The patient is a bone and ivory brush maker, and has frequently to handle brass-wiring, which is often coated with verdigris. He was very intemperate in his younger days, but has not drunk to excess for the last eight years. His mouth was quite well six days ago, when a small pimple appeared on the lower lip, which pimple, in shaving, he cut off. The next day his lip was stiff, swollen, and painful, and it has been gradually becoming worse since.

Several incisions were made into the subcutaneous tissue of the lips, and the whole face was directed to be covered with wet lint, kept moist with cold water. Wine, beef-tea, bark, and morphine. On the next day the patient was much better, had slept well, the lower lip was much less swollen, but the upper, as well as the surrounding part of the cheek, were still much inflamed; pulse 100; tongue furred and moist; bowels open by house medicine.

A few more incisions were now made into the upper lip, and the wine, brandy, beef-tea, and bark continued. On the third day it was found that the patient had passed a tolerably quiet night, but he wandered a little, and at four a.m. he was evidently worse. Countenance pale and anxious; skin warm and soft; pulse 120, sharp, but with some power. The patient takes all his stimulus; there is pain in the face; the right cheek is more inflamed and swollen; the eyelid is again puffy, but the lower lip improved; respirations frequent and loud, and small crepitation is heard behind in the lower lobes of both lungs; not audible in front.

Incisions were again made into the cheeks, which bled rather freely. The bark was continued, but opium and ether given every sixth hour. On the fourth day the countenance was anxious; pulse 120, sharp, but not without tone; cheek painful, and much as on the preceding day; the patient became worse through the day in spite of various stimulants; the pulse feebler every hour, and he was evidently sinking. Leeches to the cheek relieved him a little, and some laudanum made him sleep for three or four hours. He died on the fifth day, the face having become pale and dusky on the affected side.

Post-mortem examination two hours after death.—Body warm, and not emaciated; rigor mortis not set in; the blood that flowed from the divided vessels coagulated almost directly; the right pulmonary pleura was coated by recent layers of yellow fibrine, which readily peeled off. There were deposits of pus in the inferior lobe of the left lung, and the right was partly hepatized; there were likewise purulent deposits in the kidney; liver and spleen healthy.

Case 3.—William K——, a rather stout-built young man, aged 20, was admitted into Bentley ward, December 28, 1850, under the care of Mr. Lloyd. The lower lip was enormously swollen, livid, and in parts red and very hot. Beneath the chin were two or three pustules, and the swelling and lividity extended up the right side of the face, as far as the zygoma. The patient complains of pain, though not severe, and not to be compared with the agony he suffered two days ago; skin hot and dry; tongue coated with a thick, brownish-white fur, but moist; pulse 140, incompressible, and of moderate volume; bowels open the day previous.

The patient is a linendraper by trade. His occupation chiefly keeps him in-doors, but his general health is very good. He states that he was very well up to six days ago, when he noticed a small pimple in the middle of his lip; it was very painful on the Sunday evening, and on the Monday his lip began to swell. The greatest pain he experienced was four days before admission, since which time it has decreased. He had smoked a cigar six days previously, but the pimple on his cheek was there before the smoking.

Mr. Stanley had known a parallel case, where the patient attributed the disorder to the irritation of a bad cigar. No active treatment had been used, in the present case, before the patient came into hospital. Mr. Lloyd ordered calomel and jalap; twenty-four leeches to the lip; antimony and sulphate of magnesia; and an application of solution of borax. The leeches relieved the pain. The patient was, however, hot and restless; pulse 128, more compressible, but not feeble; bowels have not acted; tongue the same; passed some high-coloured urine. Opium was ordered to be taken at night.

On the next day, the patient expressed himself as relieved; still the respiration had on the preceding night become hurried, and the next morning he breathed with difficulty. The face was not so much swollen, but dusky; small crepitation was heard at the base of the left lung; the pulse much altered, being now wiry and feeble; the bowels have acted twice; the motions were relaxed, but natural. Mr. Lloyd now ordered beef-tea; a blister to the sternum; small doses of mercury with chalk; and to continue the draught.

From this time he got rapidly worse; the skin became cold, and bedewed with cold perspiration; pulse 150, hardly to be felt; face very livid. Brandy *ad libitum*. He died at two o'clock. No examination could be obtained.

It is extremely probable that a similar state of lung as was discovered in the second case would have been found in this, had an inspection taken place. The typhoid condition of the patients points to a morbid poison pervading the system. Whether the fatal issue is owing to exhaustion, or to the intensity of the pneumonia, is an important practical question, because the treatment must certainly be different, according as the one or the other opinion is adopted.—*Lancet*.

LUNATIC ASYLUM REPORT.

EIGHTEENTH ANNUAL REPORT TO MARCH 31, 1851, OF THE MARYBOROUGH DISTRICT LUNATIC ASYLUM.

By John Jacob, M.D., F.R.C.S.I.

It is highly satisfactory to be still able to state that the asylum continues sufficient to meet the claims made upon it for the relief of the insane poor of the district for which it has been established—a fact to be presumed from the circumstance that the daily average number of patients in the institution during the last year did not exceed 192, while as many as 200 might have been accommodated, had applications for admission to such amount been made. It does not, however, appear certain that the establishment should have been found so amply capable of accommodating all who were in a condition to require the benefits which it affords, had admission been sought on behalf of all who were in need of treatment in the asylum. There is but too much reason to apprehend that the opinion prevails amongst the poorer classes that it is to the jails they are to turn to obtain relief from the presence of insane relatives. While so much facility shall be afforded for the committal to prison of persons suffering from insanity, it is not to be expected that relatives will be likely to incur the trouble of going through the forms necessary as preliminary to obtaining admission into the asylum, and as a consequence the jails will be resorted to in the first instance, from whence the more incurable cases will be transferred to the asylum, with the disease probably increased, perhaps confirmed, by the disadvantageous circumstances under which they had been placed while in jail. It would seem that nothing short of legislative enactment is sufficient to check this evil, for it is plain that friends will apply, and that magistrates will not refuse to open the prison as an asylum for the insane, instead of endeavouring to induce parties to make proper efforts to place patients in the lunatic asylum of the district. Of the 48 patients received during the year, 19 were transferred from jails. The ill-effects resulting from committing such cases to prison—the injustice—the cruelty of the proceeding are so obvious, and have been noticed so fully in former reports, that it would

seem now only necessary to allude to the circumstance as still continuing to exist, and to require correction.

195 patients were remaining in the asylum at the commencement of the year. In addition to these, 48 were admitted, amounting in total to 243; 35 were discharged; 16 died; consequently 192 remained in the asylum at the end of the year, of whom 80 are included in the vague classification of curable, and 112 as incurable patients. Amongst those recorded as curable, it is but too probable that many cases will be found which will not recover, while amongst those noted as incurable, few (if any) are placed, who are in any degree likely to be restored to reason. From year to year the proportion of irrecoverable cases may be expected to increase, as, while the accessions to this class are continuous, the removals from it are, as a general, though not invariable rule, those which are the result of death.

The importance of early treatment in cases of aberration of mind, and the usefulness of removal to a proper asylum as soon as the symptoms become unequivocal, cannot be urged too earnestly or too frequently on all occasions when observations are addressed to the public in connexion with this subject. The fact is recognized amongst those who have experience of the disease, but is probably not sufficiently appreciated by others who are deeply interested—the friends whose assistance and guidance are indispensable for the pitiable subjects of impaired mind. Early removal should be regarded as the rule, while the exception—the retaining of the patient for a time amongst friends—should be ventured on, on careful consideration only, aided by medical advice.

Although a considerable proportion of indisposition and delicacy has existed amongst the patients, the mortality has been small as compared with what usually occurs in establishments of this kind; yet, though it be comparatively small, I cannot avoid feeling impressed with the belief that it might be rendered still less, if the arrangements for the preservation of health were more perfect in institutions of this class. 16 patients died during the year. It is remarkable that 3 at most of these died of acute disease—namely, 1 of inflammation of the lungs, 1 of inflammation of the liver, and 1 of acute dysentery. The remaining 13 were all affected with chronic disease; 2 of them suffering on admission from symptoms apparently of a fatal character, and immediately connected with the impairment of mind, chronic paralysis, on which apoplexy supervened; 5 died from chronic dysentery, and 6 from pulmonary consumption. The health of some of the 11 latter cases might possibly have been preserved, had the arrangements of the establishment been more conducive to health. No disadvantage has been greater in the institution than the imperfect provision for heating the apartments, though a sum of £197 was expended on fuel within the year. The corridors and many of the sleeping rooms are generally cold in winter, and not unfrequently damp; and when the weather is particularly damp, it is difficult to preserve the bedding in some parts of the house in a perfectly dry state. The period of the year at which the principal amount of mortality occurred is perhaps worthy of note in connexion with this particular point. No less than 10 of the 16 deaths occurred in the months of February, March, and April, leaving a proportion of nearly one-half of the whole to be distributed over the other nine months of the year. From this fact it may be presumed that the depressing effects of the winter season on the vital powers are especially remarkable in such an institution as ours, and that every reasonable precaution should be adopted to maintain it in a healthful state. Of those who died, six had been inmates for a period of over fifteen years, two over eight, four from two to eight years, and four under six months, three of the latter having been in a state of utterly broken down health on admission, one of whom was aged 74, and another 64.

Some improvements have been effected in the structural arrangements of the house: the most important and useful was the raising of the chimney of the steam kitchen, which was previously so low that the smoke and vitiated air had been discharged in considerable quantities into several apartments, occupied both by day and night; the advantages resulting from this improvement have been very remarkable. The ventilation has also been much improved by the general introduction of perforated zinc as upper panels in the doors of the day-rooms, at the stair heads, and in other places, this material being well adapted for the purpose, as allowing the passage of light and air, the latter in a mild current, without any unsafe draught. The doors of the rooms used for the occasional seclusion of violent patients have been carefully padded—an arrangement which is very useful as preventing bad consequences to any patient who might strike at the door when placed in the room; and also as relieving the other patients in the division from the disturbance which knocking at an uncovered door should cause. There is not, however, any fully padded room in the establishment, nor has it as yet appeared that any ill-effects have resulted from want of such preparation. Five beds have been constructed for the special use of patients of very violent character, or who suffer from severe epilepsy. The bed consists of canvass so strong that no man could tear or jump through it; this is swung on neat, well executed, proved chains, which are stretched across the end of the sleeping room, at a distance suitable for the breadth of the bed, the chains being attached to strong eyes of iron, secured into the wall, by means of a hook at each end, one of which is so made as to receive a padlock when set into its place, and thus the removal of the chain is prevented unless when the lock is opened. By this arrangement the canvass can be easily taken off, for the purpose of being cleansed or repaired when necessary, as its mode of attachment consists simply of a strong wide hem at each side, through which the chain is run. The head of the bed is maintained elevated higher than the foot, by having the eyes set in the wall nine inches higher at one end than at the other. A mattress or bedtick lightly filled with straw is laid over the canvass, with bedclothes suited to the case. This bed is most comfortable and secure; the patient is preserved from risk of injury against a bedstead; and as the bed is hung so close to the floor as merely to prevent contact, the patient incurs neither danger from a fall out of bed, nor from lying with the head and shoulders hanging down as has occurred under my observation in private practice to a person suffering from epileptic fits. The plan of having the head of the bedstead raised higher than the foot has been adopted with advantage in all the ordinary bedsteads which have been procured for some time past. Gutta percha chamber utensils have been introduced for the use of violent patients, and are particularly well adapted for the purpose, as being both economical and safe. Some difficulty having been experienced in procuring them of suitable size when first adopted, a supply was made on the spot from strong sheet gutta percha moulded over delf; these, however, did not prove as serviceable as articles manufactured by the company, as the joints of the home-made work did not as effectually resist the efforts of violent patients as those of the vessels made at the company's works.

I should not omit to express my unabated confidence in the non-restraint system of treating the insane. An experience of over seven years in an establishment for 200 patients would appear to justify the formation of a mature opinion on the subject. During that period instrumental restraint of any kind has not been practised in the asylum; violent patients have been merely removed from the company of the others to a secure room till the period of anger passed by, the average duration of such seclusion being about three quarters of an hour. On those occasions when a disposition to destroy clothing or bedding has been manifested, articles have been used of such strength as to resist the utmost violence that the patient could apply. Having previously known a system in operation for several years in this asylum, of which instrumental restraint formed a part, as circumstances appeared to require, to a degree which would not have been regarded as severe according to the practice which then generally prevailed in the treat-

ment of insane, and having marked the gratifying effects which resulted from a total and unconditional abolition of such practice, I feel bound to continue to offer my testimony in favour of a general abandonment of the use of instruments of restraint.

It is, I apprehend, not out of place here, nor inconsistent with the nature of such a report as this to notice, with sentiments of profound respect, the loss which the institution incurred by the death of my late worthy brother officer, Mr. Abbott, who opened the institution on 14th of May, 1833, and continued to conduct its affairs as manager till incapacitated by illness, which terminated in his death on the 3rd of August, 1850. His amiability of disposition and personal good qualities, as well as his uniform and persevering attention to the duties of his office, were too generally appreciated to be in any degree enhanced by any observation of mine, though it falls to my lot to place the lamented circumstance on record in our annual reports. In filling up the vacancy thus created in the management of the establishment, the advantage of a resident physician, in the person of my colleague, Dr. Burton, has been extended to the institution—an arrangement which will, no doubt, prove as beneficial to the inmates as it is agreeable to me to enjoy the official coöperation of a member of my own profession.

The following table presents a general view of the state of the patients for the year :—

TABULAR VIEW OF THE STATE OF THE PATIENTS FOR THE YEAR ENDING 31ST MARCH, 1851.

	Remaining on the 31st March, 1850.	Admitted to the 31st March, 1851.	Total under treatment within the year.	Discharged, cured or relieved.	Removed unrelieved by friends.	Total discharged.	Died.	Remaining in Asylum on 31st March, 1851.	Of whom are supposed to be curable.	Supposed incurable.

The absence of correspondence of the numbers remaining in the asylum at the end of the year, as compared with the numbers under the several classifications of the disease in the preceding columns, is accounted for by the variations which from time to time occur in the character of the cases.

BLEACHING OF IVORY BY SULPHUROUS ACID. — Ivory knife-handles, which have become quite yellow from use, being left for from two to four hours in a watery solution of sulphurous acid, become white again. The acid in the gaseous form makes the ivory crack.—*Phar. Jour.*

THE MESOPODIUM OR SADDLE-STICK.

By T. TWINING, Esq., jun., of Twickenham.

MR. TWINING has forwarded to us the following particulars respecting his invention; and we have no doubt that it will prove of great value for the purposes for which it is intended :

The invalid emerging from a long confinement to his couch may truly be said to appreciate more the blessing of being able to get about with the assistance of crutches, than a person in good health does the full enjoyment of his limbs. The object of the mesopodium is to place this within the reach of many who have not yet attained the degree of convalescence usually required, and of many indeed who could perhaps never expect to attain it.

In order to use crutches with comfort, it is requisite that the invalid should have strength enough, either in one leg or in the two together, to bear the whole weight of his body whilst he brings forward his two crutches *simultaneously*, otherwise he is obliged to bring them forward *alternately*, whilst he hangs with nearly his whole weight, first on one shoulder, and then on the other, in a manner at once fatiguing and injurious. This is entirely obviated by means of the simple apparatus proposed, on which the invalid rests comfortably seated, although perfectly erect in posture, whilst he brings both his crutches forward.

It was towards the beginning of 1842, that I was induced, by that necessity which is truly said to be the mother of invention, to make my first attempt in this mode of progression; but it was not till 1844 that I hit on the idea of obtaining a comfortable approximation to the shape of a saddle, by the very light and simple means of a small oblique board.

It will be noticed that the supporting stem does not consist of a single straight stick, but of two thin slips of wood curved to suit the form of the legs. Besides the advantage of rendering the apparatus less unsightly, it is astonishing what light and slender slips are found to be, in this way, perfectly adequate to support the weight of the human frame.

If the wooden saddle is accurately shaped, it may be used even without stuffing; but I consider it preferable to add a little stuffing covered with velvet, which can be done without materially adding to the weight of the apparatus, which, when complete, does not weigh more than fifteen to twenty ounces. In consequence of this lightness, which is one of its most essential advantages, it is scarcely felt by the person using it; and the legs being slightly pressed against it, it follows their motions without any effort being required to keep it in its place, especially if a strip of velvet be fastened on the outside of each of the slips, with the nap downwards, so as to present a rough and somewhat adhesive surface to the cloth of the trousers.

I shall not for the present enter into the practical details of the use of the mesopodium, or enumerate the very great advantages which I have personally derived from it for the last five or six years; the former will be best understood, and the latter better appreciated, by seeing the apparatus used by some person who has acquired practice in the use of it; for in this, as in everything else of the kind, it is only practice that makes perfect.

It will then be at once perceived that the use of the saddle-stick, either in its present form or with such modifications as will readily suggest themselves, is applicable to many cases in which the limbs are incapacitated for bearing their natural burden, either by the effects of accident or by disease.* It will further be perceived that the patient may rest just as much or as little of his weight as he pleases on the artificial support thus afforded him; and this is a consideration of no little importance, for provided there be healthful tendencies, and if nothing unfavourable should intervene, the chances are that a judicious apportionment of the amount of effort to the amount of strength, and a very gradual and cautious increase of exercise, will most essentially conduce to the progress of his recovery. Day by day he will rest more on his limbs and less on their artificial coadjutor, till the time comes, not for kicking away the mesopodium, but for laying it aside to be gratefully preserved as a memento of some of the most soothing of human enjoyments—those of convalescence.—*Lancet.*

* In cases of spinal debility, which would preclude the use of crutches in the common way, two straps passing over the shoulders may be fastened to the saddle part of the mesopodium before and behind, with buckles in front, to allow of lengthening or tightening at will,

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, AUGUST 13, 1851.

MEDICAL CHARITIES' BILL.

THIS measure is now the law of the land, but not having been printed since it received the royal assent, we postpone laying it before our readers in full from the bill sent up to the Lords by the Commons, although we do not believe that it has undergone any alteration whatever. It contains 22 clauses, and provides as follows:

1. The crown to appoint two persons; "*one, a physician or surgeon of not less than ten years standing,*" with the title of MEDICAL COMMISSIONER, who, with the other Poor-law Commissioners, shall be the Poor-law Commissioners for Ireland.

2. Provides that orders for the formation or alteration of a dispensary district, or for framing or revoking rules, shall be signed by not less than two Commissioners.

3. The Commissioners may appoint "so many fit persons," as the Lords of the Treasury shall sanction, "being practising physicians or surgeons of not less than seven years standing," to be Inspectors "to assist in carrying out the provisions of the act."

4. Salaries to be settled and paid by the Lords of the Treasury.

5. Neither Commissioners nor Inspectors shall practise as physician or surgeon, or *in any other professional capacity.*

6. The Guardians are to divide each union into "so many dispensary districts as may to them appear necessary;" subject to the approval of the Commissioners; and to alter such districts if required by the Commissioners; but they are not to divide any electoral division. After a day to be named, the cost of medical relief, within the dispensary district, all salaries and charges included, shall be charged on the electoral division or divisions comprised therein: and "the Commissioners shall declare the number and qualifications of the officers to be appointed for the service of each such dispensary district, and the number of persons who shall be members of the committee of management."

7. The Guardians to elect, if necessary, a sufficient number of ratepayers of £30, resident in each district, who, with the guardians residing or owning property therein, are to be the dispensary committee, but not to exceed the number named by the Commissioners.

8. The Guardians are to provide "a house, building, room or rooms to be used as a dispensary or office for the district medical officer, and the meetings of the committee, and such medicines and medical appliances as may be necessary for the medical relief of the poor in the district. The dispensary committee are to appoint (subject to the approval of the Commissioners) *one or more* medical officers for the district, with such qualifications as the Commissioners shall determine, and with such salaries as the Guardians (with the approval of the Commissioners) shall determine; and the Commissioners may regulate the amount of salaries, and the time and mode of payment; and may remove a medical officer, on sufficient grounds, and direct the committee to appoint another in his stead."

9. Members of the dispensary committee, relieving officers, and wardens of district, to issue tickets for medical relief; upon which the medical officer is to afford medicine and advice or to attend to poor so provided; but if a patient be declared an unfit object by the committee, such ticket shall be cancelled.

10. All provision now made by law for affording dispensary relief, from poor-rate or presentment, shall cease, except to pay expenses already incurred; and all funds and property arising from bequests shall be applied to the support thereof, according to the trusts of such bequests. Salaries now payable to infirmary surgeons from the treasury are to be withdrawn on the death or removal of the present surgeons, but Dublin hospitals are exempted.

11. Provides that dispensary officers shall not supply any matters for the use of the institution.

12. The Commissioners are to frame general rules for the government of the district, and the guidance and control of the guardians, the committee, and officers.

13. Orders that the dispensary surgeon shall vaccinate as required by vaccination act, and that all present contracts for vaccination shall cease.

14. Is as follows:—"When, on the formation of any district under the provisions of this act, a medical practitioner shall be in possession of a medical office connected with any dispensary subject to the authority of the said Commissioners, and situate in the locality included in such district, it shall be lawful for the Commissioners, if they shall think fit, to declare him to be, in the first instance, the medical officer or one of the medical officers of such new district; and so likewise when two or more medical practitioners shall be circumstanced as aforesaid, in case the like number of medical officers is required in such new district, it shall be lawful for the said Commissioners, if they shall think fit, to declare such persons to be the medical officers of such new district; but in case a smaller number of such officers shall be required for such district, then it shall be lawful for the said Commissioners, if they shall see fit, to nominate such persons, or any of them, as the persons from whom a selection shall be made for a medical officer or officers under the provisions of this act, by the parties entitled to appoint to such office; and it shall not be necessary for the said Commissioners, unless they think fit, to reject any such medical practitioner so in possession of any such office before the formation of such district, by reason of the want of such qualifications as may be required by them in other cases."

15. District surgeon to examine dangerous lunatics and attend the bridewell and supply medicines to be paid for, but the Commissioners may increase his salary on account of this duty.

16. The Commissioners may require the attendance of all such persons as they shall think fit respecting any matter connected with the execution of this act, relating to any dispensary subject under this act to them; and make inquiries, administer oaths, and enforce the production of books and papers, but no person is to be compelled to travel more than thirty miles from his place of abode by the Commissioners, or more than five by the Inspectors: these powers are not, however, to extend to medical institutions supported by private endowments or subscriptions.

17. Provides penalties for giving false evidence, or refusing or neglecting to attend or to produce papers.

18. Authorizes Inspectors to enter at all times into, and to inspect dispensaries, to attend meetings of committees, and to take part in them, but not to vote; and also to enter, inspect, and report upon any infirmary, hospital, or medical institution, supported in the whole or in part by any public funds, rates, or assessments.

19. Declares the Commissioners to be Commissioners for executing in Ireland the powers of the Nuisances Removal and Diseases Prevention Act.

20. Orders annual reports to be made to Lord Lieutenant to be laid before parliament.

21. Is the interpretation clause; and 22 directs that the act is to take effect from the 1st of October next.

CASE OF POPLITEAL ANEURISM CURED BY COMPRESSION OVER THE TUMOUR.

By H. N. Bennett, M.D., of Bethel, Connecticut.

The following case possesses no intrinsic value, with the exception of the method of cure, which consisted in pressure applied directly over the aneurismal tumour, and it is for this reason only, that I have thought it worthy of record. Perhaps the fact of the patient having *cured himself* affords some additional interest; as, I believe, in this respect, the cure is unique:—

Thomas J. Elwell, a blacksmith, aged 30 years, during the winter of 1842–3, suffered from pain about the knee-joint, which he supposed to be of a rheumatic character, and applied only domestic remedies for its relief. After a walk of twenty-two miles over frozen ground, the pain and lameness of the knee increased to such a degree, that he consulted me in reference to it. Upon examination, I immediately detected a pulsating tumour in the popliteal region, nearly the size of a hen's egg, and having all the characteristics of aneurism. This was in the month of March, 1843. At the end of five or six weeks from this date, the tumour had increased considerably in size, so much, that I advised my patient to submit to ligation of the femoral artery at once, as the nature of the difficulty could not be doubtful, and as I had at that time little confidence in any other mode of treatment. Feeling unwilling to endure a surgical operation, he soon went to New York for further advice. He consulted Drs. Mott and Rogers, who both gave him the same opinion which I had done, and urged him to remain at the New York Hospital for operation. He then passed over to Staten Island, on a visit to his friends, where he consulted some physician, whose name I cannot recall, who also pronounced it a case of aneurism, but recommended him to try the effects of pressure upon the tumour. He returned home and commenced the application of pressure *himself*, by bandaging the limb from the toes to the knee, and placing a compress of folded cloth directly upon the pulsating tumour. He persisted in this course for two or three months without the least benefit, when he determined to substitute a firmer compress. Instead of folds of cloth, folds of *sheet-lead* formed the nucleus of his compress, which was applied in the same manner as before. I called upon him occasionally to watch the progress of his treatment, and after the end of ten days after the application of the lead compress, I found him suffering much pain in the knee-joint, from the severe pressure which he had made, but no diminution in the size of the tumour or the force of the pulsations, the latter being readily felt through the compresses when applied with all the force which he could endure. I advised him to discontinue what I considered a hazardous proceeding, and to abbreviate his sufferings by submitting to the usual operation. Notwithstanding, being a man of very strong resolution, he determined to pursue this course still longer, and abide the issue. At this time, however, he threw aside the lead compress, and filled its place with *a ball of caoutchouc*, which he bound upon the tumour with all the force he could endure. Not long after, perhaps two or three weeks, I called again to see him, and was much surprised upon examining the limb (which he exhibited with no little triumph) to find the tumour much diminished in size and the *pulsation gone*. I could also distinctly feel several arteries pulsating about the knee-joint, evincing an increased development of the anastomosing branches of the femoral. From this time, the tumour in the popliteal space was gradually absorbed, and at the end of a few months had entirely disappeared. This man has since died of phthisis in New York city.

I think there can be no question in this case, in reference to the diagnosis; since the most experienced surgeons in the country examined the patient, and had no hesitation in pronouncing it a case of aneurism, and recommending ligature of the femoral artery.—*New York Jour. of Med.*

BIRTHS AND DEATHS IN LONDON,

Poisoning by Arsenic.—Mr. W. Odling says: Wash out the stomach, by means of the double action stomach-pump, with a solution of chromate of iron or alumina, or a mixture of permanganate of potassa solution, or with hydrate and acetate of ferric oxide, or with hydrate and acetate of alumina. By these compounds the soluble arsenious acid is immediately converted into insoluble arsenic acid, or into the insoluble sesquiarseniate of alumina, iron, or chrome. Ten grains of the permanganate of potassa may be mixed with half a pint of the aluminous emulsion, under which circumstances, its irritant action would be very trifling, not more than that of an ordinary sulphate of zinc emetic.

Erratum.—In the article "Bell's Grave," 16th of July last, for "Kallow Park," read "Hallow Park."

PREPARATION OF OILY EMULSIONS.

The preparation of oily emulsions succeeds better, according to Overbeck, if the following proportions of gum be employed. Different oils conduct themselves differently when rubbed down with gum; castor oil differing most in this respect from the other oils. In order to obtain a perfectly milk-white emulsion of castor oil, two drachms of gum are to be mixed with three drachms of water and one ounce of castor oil, which is to be poured, by a fine stream, into the constantly stirred mucilage. Any additional quantity of water is then readily taken up by the emulsion, which may also be prepared with only four scruples of gum, but without becoming quite white. For other oils half their weight of gum is required, and the quantity of water must be half the total weight of oil and gum. Thus, one ounce of oil of almonds is to be first rubbed down with half an ounce of gum, and six drachms of water are then to be added at once. The so-called crackling (kracken) of the emulsion appears here in a higher degree than after the usual method, and is a favourable symptom of the uniform distribution of the oil in the water.—*Phar. Jour.*

THE MIDLAND RETREAT,

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY,)

For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System.

Under the direction of Dr. JACOB,

Physician to the Maryborough District Lunatic Asylum, (containing 200 patients,) Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

THE ROYAL MEDICAL HALL,

64, DAME-STREET, DUBLIN.

☞ *Change of Proprietorship.*

BEWLEY, OWEN, AND CO., APOTHECARIES,

(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS,

will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick-room and nursery.

*** GENUINE COD-LIVER OIL,

of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

DISPENSING OF MEDICINE.

G. OLDHAM AND CO.,

PHARMACEUTICAL CHEMISTS, AND APOTHECARIES,
From BEWLEY and EVANS',
No. 107, GRAFTON-STREET, DUBLIN,
(Corner of Suffolk-street),

BEG to return their grateful acknowledgments to the Medical Profession for the support they have hitherto received, and which they will regard as a fresh motive for exertion. Abstaining altogether from visiting as Apothecaries, except for the application of Leeches, Cupping, and such operations as are performed under medical advice, they will continue to devote themselves exclusively to the duties devolving on the pure Pharmacien.

Having had much experience in Practical Pharmacy, and being resolved to spare neither trouble nor expense in order to have every article of superior quality, they hope by attention, "carefulness," punctuality, and moderation of charges, to commend themselves to the approbation of those who may entrust them with their commands.

☞ *G. O. and Co. invite attention to their present stock of Surgical Instruments, all of which are manufactured on the most modern and improved principles.*

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the city of Dublin.

HISTORICAL SKETCH OF THE CONNEXION OF ASTROLOGY WITH MEDICINE.

By M. Donovan, Esq., M.R.I.A.

(Continued from p. 102.)

Contemporary with Agrippa was Girolamo Fracastoro, a learned physician, astronomer, and astrologer. He was born at Verona in 1483; at the age of 19, he was appointed to the professorship of logic in the University of Padua, which, in a few years after, he relinquished, in order to cultivate the study of medicine. He acted as physician to the Council of Trent, was soon regarded as the most skilful practitioner in Italy: and was the inventor and preparer of the long celebrated medicine, Diascordium. Far from confining himself to these pursuits, he distinguished himself in mathematics, cosmography, astronomy, and other branches of natural science. Perhaps the most remarkable of his endowments were his skill and elegant taste in the composition of Latin poetry. Such excellence did his verses possess that Sannazarius, himself a writer of exquisite Latin poetry, gave the preference to that of Fracastoro—a judgment in which others have coincided. His subject was a singular one, and required no small genius to elevate it to the heights of Parnassus: but he was equal to the task: it was entitled "Syphilis, sive de Morbo Gallico," and was dedicated to Cardinal Bembo, another writer of excellent Latin verse. Mr. Roscoe (Life of Leo X.) has given a beautiful translation into English verse of a part of this poem, just sufficient to excite regret on the part of the reader that he did not present the world with the whole in the same exquisite style. Fracastoro died in 1553; a splendid monument was erected to his memory in the cathedral of Verona, and a statue in the city, at the public expense. Tiraboschi expresses himself thus strongly concerning his poem de morbo Gallico, "non vi ha poema a mio credere, in cui si veggano sì ben combinate forza ed eleganza di stile, leggiadria d'immagini, e profondità di dottrina, e ottimamente dice il celebre Guarino, che in esso la Fisica e la Poesia l'estremo delle sue forze han consumate."

In the time of Edward the Sixth, about the middle of the sixteenth century, the learned physician Cardan was invited to England to calculate the nativity of the king. It is worth while to notice the short career of this gifted, eccentric, immoral, and extraordinary man.

Jerome Cardan was born at Pavia in 1501: his mother was not married at the time of his birth, and unsuccessfully endeavoured to cause abortion. After a preliminary education he was chosen professor of medicine in his native city, and soon after filled also the chair of physic at Bologna. He practised as a physician with the greatest success, and wrote some severe animadversions on the opinions and practice of his professional brethren; in short, he wrote himself up by decrying others. An anecdote is told of him which at once evinces his pre-eminence and eccentricity. It happened that the Archbishop of St. Andrew's in Scotland laboured under an asthma which for ten years defied the skill of all the chief physicians of the age. The reputation of Cardan being now at its height, he was called on to attend the Archbishop; was successful: was amply rewarded; and on taking his leave he congratulated the Archbishop on his recovery, but assured him that although he cured his disease, he could not prevent his being hanged.

Whatever might have been his eminence as a professor and practitioner of medicine, his mathematical knowledge conferred on him infinitely greater celebrity, and at length obtained for him the professorship of mathematics at Milan. There is scarcely a subject on which he did not write: medicine, natural history, materia medica, mineralogy, mathematics, metaphysics, logic, physics, ethics, judicial astrology, are amongst the subjects to be found in his works. He wrote four books on the interpretation of dreams (many of them his own) which are ridiculous and discreditable to his talents and common sense.

Notwithstanding such acquirements, Cardan was an ill-conducted person. Irregular, eccentric, and violent in all his actions, he was a continual sufferer, so much so that he confesses he often meditated suicide. He made no secret of his errors, but attributed them to necessity occasioned by the influence of the stars. He was a professed

astrologer; he calculated nativities, foretold events, interpreted dreams, and practised all the trickery of the lowest impostors in the art. According to his own account, he was twenty years investigating why some die of fever and some recover. Beside all this, he was an infatuated, irreclaimable, and unsuccessful gambler. His children, sprung from a bad stock on both sides, were worse than himself: one of his sons married a woman of bad character; and suspecting her fidelity, he poisoned her, and was beheaded for the murder, the father defending his son's crime. Cardan died as he lived, a reckless impostor; he foretold the day of his death, but having survived it, to the scandal of his art, he was determined to redeem its character; and prophecying once more, he made sure of the result, by starving himself to death, in the 74th year of his age; thus, as was said, losing his life to save his credit.

It is said that, when he was born, his head was full of black curled hair. (Bayle.) During life he was the subject of a violent impetuosity of temper which he was in the habit of appeasing by the agency of pain; this he inflicted by biting his lips, pinching his arms, and twisting his fingers even to tears. In cases of excessive violence of temper, he scourged himself with a rod, bit his arms severely, and fasted. He declares that he could lose his senses when he pleased, and pass into an ectasy; he could then perceive that he was insane (extra meipsum), and perhaps the reader will suspect that he was seldom otherwise. Butler, the unsparing satirist of human folly, thus notices his opinions:—

> "Cardan believes great states depend
> Upon the tip of the Bear's tail's end;
> And as she whisks it towards the sun,
> Strews mighty empires up and down."

Such was the man to whom the sixth Edward of England applied for the revelation of his destinies and the disclosure of the intentions of Providence.

The readers of English history are aware of the extraordinary predilection manifested by Queen Elizabeth for Dr. Dee, a man of great natural endowments and possessed of considerable acquirements. He was an accomplished mathematician and wrote on geometry; but degraded himself by professing astrology, magic, communion with spirits, sorcery, and alchemy: and above all, by associating himself with an infamous fellow named Edward Kelly, who had lost his ears, was pilloried for forgery; and whose practice it was to disinter the dead, in order, as he said, to extract from the corpse those secrets of which death had rendered it cognizant. Dee and Kelly practised as confederate magicians.

No man was ever more celebrated for supposed supernatural knowledge than Dr. Dee; his fame spread over Europe, and crowned heads vied with each other for the possession of a man who was believed capable of penetrating futurity, controlling nature, and creating unbounded wealth. According to his own statements, the German Emperors Charles V., Ferdinand II., Maximilian II., and Rodolph II., made him liberal offers of settlement in their dominions. The Czar tendered £2000 a year for his services. Queen Elizabeth gave him substantial proofs of her favour; he held from her two livings, yet was poor; she sent him physicians when he was sick; appointed commissioners to ascertain his circumstances; invited him home when he was a degraded wanderer practising imposture on the credulity of foreign princes; and in 1594 obtained for him the chancellorship of St. Paul's; could she do less for a man who, according to his own account, had been honoured with a conference with the archangel Uriel?

So superstitious was the Queen, and so great her reliance on the astrological knowledge of Dee, that she would not consent to be crowned until he had determined the most proper day by the aspect of the stars. On a certain occasion the Queen being ill, Dee advised her to beware of Whitehall; she therefore resolved to go to Richmond. When taken with her last illness, she would take no medicine; and for a long time would on no account go to bed, in order to elude, as was supposed, a prophecy, which did not require witchcraft to foretel, that she would die in her bed. The seer, however, turned out to be more correct than a Spanish astrologer, who predicted that the Queen should pass her 75th year. (Frederick Von Raumer.)

Notwithstanding Dee's poverty, he professed to be in possession of the philosopher's stone; and in 1589 the Queen granted him a licence to practise transmutation—a mode of enrichment which did not exactly meet the doctor's necessities. He had a stone, presented to him by the angel Uriel, in which he professed to keep a spirit imprisoned. With this spirit he pretended to hold communion, and thus to obtain a knowledge of future events. When consulted by those who would pry into futurity, he referred to the stone: in it various supernatural beings appeared; he conversed with them through the intervention of Kelly, and acquired for his dupe the necessary information. This remarkable stone is still to be seen in the British Museum, but the imprisoned spirit is no longer communicative; it proves to be a gift unworthy of an angel, being merely a lump of polished cannel-coal.

About this time it was a common practice for impostors who pretended to discover the secrets of the future to keep a mirror, or crystal, or transparent stone, sometimes a large beryl, in which might be made to appear, as was pretended, an angel, or spirit, or demon, or any person living or dead, as the case might be. This was done by an invocation: the angels Michael, Gabriel, Raphael, Uriel, were chiefly in requisition; and a selection was made according to the fancy of the invocator. The invocator did not himself see the apparition in the crystal, but employed a deputy called a *speculator*, who of course saw whatever was required of him to see. The invocator should be a person of *piety*, or perhaps nothing would appear, not even a demon. Lilly mentions an invocator whose habit it was, when the spirits proved refractory, and would not appear in consequence of his debaucheries, to curse them and annoy them with fumigations of various kinds. He adds, that Dr. Dee's speculator, Edward Kelly, was very vicious; that on this account the angels were not obedient to him, and would not willingly answer questions proposed by him. The invocations were of such kind as

> "Per virtutem illorum qui invocant nomen tuum
> Hermeli—mitte nobis tres angelos, &c."

Another was "O Micol, O tu Micol, regina pygmæorum veni." On pronouncing which the queen of the fairies attended promptly.

Dee's supposed skill in the black art had caused him much trouble; he had been incarcerated, tried, and acquitted for practising enchantments against the life of Queen Mary: his library and curiosities were destroyed, and his house shattered by a mob. Notwithstanding that he possessed, as he said, the elixir vitæ, he died (1608) in the 81st year of his age, universally despised by all thinking men. Such had been his poverty that to obtain a dinner he was frequently obliged to sell some book or other article.

In the book entitled "A true and faithful relation of what passed for many years between Dr. J. Dee, a mathematician of great fame in Queen Elizabeth and King James their reignes, and some spirits," with a preface by Meric Casaubon, son of Isaac Casaubon: London, 1659, folio,—we learn that, while at Prague, Dr. Dee besought the angel Gabriel that he would declare a certain remedy for his wife's disease, who was sick and threatened to death and her child in her womb. Edward Kelly as usual was the inspector of the stone, in which the angel Gabriel having appeared, the celestial messenger gave a statement of the cause of her disease which none but an angel could comprehend; and also this prescription, "take pure wheat a pinte; one pheasant cock alive; eleven ounces of masculine amber (which is the white amber); an ounce and a quarter of turpentine:—break the cock in pieces with a pestel (his feathers pluckt off); pound the amber small: put all this into a gallon of red wine: distil with a fire of the second heat: still it again the second time, the feces being cast away." After fasting forty hours from

meat, this medicine is to be divided into three parts, she is to drink the first part gradually; of the second part let her make a sauce for five or six meals; the "last part let her use in absconditis," and she shall have health. E. Kelly profanely observed to the angel that he might make the table cure her if he liked. The prescription merely amounted to administering to the patient a dose of brandy equal to one-third of the whole quantity procurable from the distillation of a gallon of wine which would be about half a pint,—a tolerable allowance for a lady in that interesting situation.

At another meeting, the angel Gabriel gave but an indifferent account of physicians; he says, "physick is in very deed the true and perfect science of the natural combination, and proportion of known parts, answering in graduation real, to one principal and defined; is therefore above the capacity of such as are wordlings, and do hunt after money more than the truth of GOD's spirit." This from the angel Gabriel is a poor character of the doctors.

Perhaps the most extraordinary compact ever entered into by human beings was made between Dr. Dee, E. Kelly, and their wives. They believed, or affected to believe, that GOD himself, by his messenger, had signified his divine will that they four should enjoy everything in common, that the wives were to be common to the two men, and that GOD counteracted his own commandments in their case for some wise and inscrutable purpose which it was not for them to resist. They drew up the following remarkable document: "Note and remember that on Sunday, the 3rd May, 1587, I, John Dee, Edward Kelly, and our two wives covenanted with GOD, and subscribed the same, for indissoluble and inviolable unities, charity and friendship, keeping between us four, and all things between us to be common, as GOD by sundry means willed us to do. Ad Dei honorem, laudem et gloriam in fide et obedientia Factum esto. Amen." (p. 21 of the part at the end of the volume entitled Actio tertia.) The whole transaction is accompanied by prayers for wisdom, illumination, and instruction; with so many doubts, hesitations, resolutions, and retractions that one is inclined to believe that all the parties were deranged, except perhaps Kelly, who affected to be the most unwilling party, although he was the expounder of the shew-stone, as it was called, and affected to see in it a female spirit, whom he called Madini, who inculcated the foregoing detestable community. It is barely possible that Dee was the dupe of Kelly, and committed these crimes under the mistaken conviction that he was but obeying the divine will; but it is perhaps more probable that Dee was insane.

Edward Kelly, Dee's *speculator*, was born at Worcester, and was bred an apothecary, was a good proficient in chemistry, and pretended to have the grand elixir. Alasco Palatine of Poland, Pucelli, a learned Florentine, and Prince Rosemberg of Germany, the Emperor's Viceroy in Bohemia, were long members of a society with him and Dr. Dee, and often present at their pretended meeting of apparitions, as was once the King of Poland himself. But Lilly, says Kelly, was so wicked that the angels would not appear to him willingly, nor be obedient to him. Weever says that Kelly lost his ears at Lancaster; and raised a dead body in that country by necromancy: "that Queen Elizabeth sent for him out of Germany; but climbing over a wall at Prague, where it is reported he was imprisoned for a chemical cheat put on the emperor, he broke his legs, and bruised himself so that he died soon after. His spirits told him (1584) he should die a violent death" (Gray on Hudibras), as was indeed easy to foresee.

The chief favourite of King Charles II. was the celebrated Dr. Elias Ashmole, who derived honours and emoluments as much from his impostures or self-deceptions, as from his real acquirements. Not only were favours lavished on him by his own sovereign, but foreign princes presented him with valuable tokens of regard. His professions and avocations were numerous. He was a doctor of physic by diploma from the University of Oxford, an astrologer, an alchemist, and a chemist; became a solicitor in chancery, an attorney in the common pleas, and a lawyer; he was a captain in the army, comptroller of the ordnance, and commissioner of excise; was appointed Windsor herald, keeper of the king's medals, secretary of Surinam, accountant-general in the excise, along with many other offices. He studied mathematics, natural philosophy, astronomy, botany, and antiquities; in the last of which he became eminent, and made the collection well known under the name of the Ashmolean Museum at Oxford. He was the author of many truly learned and ingenious works, notwithstanding his pretensions to superhuman knowledge. He resided in the Middle Temple, and possessed there a library, and a cabinet containing 9000 coins; all of which were destroyed by fire. Ashmole, notwithstanding his rank and learning, was the friend of Lilly, and of that impostor's infamous associates; he even presided at their annual orgies.

Lilly was perhaps the most celebrated of all the community of knaves styled astrologers; for astrology was his only profession before he obtained his licence to practise medicine. He was born in 1602, and at the proper age was hired as a servant by a gentleman in London, who at his death settled £20 a year on him. But Lilly, not content with this advantage derived from his master, so ingratiated himself with the widow, that within the same year they were married. In a few years the lady died, and left him a competent fortune. He then betook himself to the study of astrology, but was very little noticed until 1643, when, to use his own words, he was "destined by a good lady to give judgment upon a most noble gentleman's urine, who was not well." Fortune favoured the career of Lilly by several coincidences. He foretold that in 1647 "he would be in great danger;" and in that year the plague visited London. In his book called "Monarchy or no Monarchy," he introduces several ill-executed woodcuts; one of which represents a man digging graves, several shrouds lying on the ground. In the next page is represented a river with shipping, the banks lined with houses all wrapped in flames. It so happened that in 1665 the plague again broke out in London, and in twelve months carried off 68,000 persons; and the next year, corresponding with the cut in the next page, representing a conflagration, the great fire occurred, in which 13,200 houses were burned.

Such fortunate hits as these, as may well be supposed, gave, in the eyes of the vulgar, a superhuman character to Lilly. Nay, with the most exalted personages in the land, he was not considered an ordinary man. His astrological papers were cried about the streets of London, and translations of them were similarly circulated in Hamburgh. During the distracted reign of King Charles I., no step was taken at court without reference to him. One time he prophesied favourably for the parliament; another time for the king; and from both sides he secured his reward. While the king was at Hampton Court, Lilly was consulted as to where his majesty might retire for safety; and again, in 1648, when the king was in the Isle of Wight. Indeed the king took scarcely any step without his advice. Beside occasional gratuities, the parliament settled on him a pension of £100 per annum, as Butler says, for fortelling* whatever they directed; but as Lilly himself says, for obtaining secret information from France. During the siege of Colchester he was sent to encourage the soldiers: he assured them that the town would soon be taken, and accordingly so it was. The King of Sweden sent him a gold chain and medal, worth £50, because he was respectfully mentioned in his Almanack; and he had actually the nomination of an ambassador to the court of Sweden. In 1660, at the restoration, he was taken into custody by order of the House of Commons, and examined concerning the person who cut off the king's head—

* "Do not our great reformers use
This Sidrophel to forbode news?
And has he not point-plank foretold
Whatsoe'er the close committee would."
[Butler's Sidrophel was William Lilly.]

a question never since settled. His pardon was then granted him. Echard says he was one of the close committee appointed to consult about the execution of Charles. In 1666 he was examined by the House of Commons concerning the cause of the great fire, which had turned out so exactly according to his prediction; but he merely replied that his art had enabled him to foresee the calamity without knowing the year when it was to happen; that he knew not if the fire were caused by design, and that he believed it was done by the finger of God. Another time he was called before the House for publishing in his "Anglicus" that the people and soldiery would join against the parliament, and only escaped punishment by producing six copies which he had privately got printed without the offensive passage, and declaring the others to be forgeries.

In order to extend the benefits of his art, at least to himself, Lilly gave a course of public lectures; which, however, he took care should not raise up rivals, by being generally intelligible: he himself was the only person that benefited by them. His own instructor had been a drunken Welsh clergyman, named Evans, of the most abandoned character, who, nevertheless, professed communion with angels. Evans was the inventor of the antimonial cup so often alluded to by Lilly, and warranted to be the "phœnix and miracle of all physical miracles." This exemplary "minister of God's word," as he styled himself, declared that the cup contained, "mystically and essentially, the quintessence of all minerals and vegetables, and magnetically sympathized with all animals." It was calculated to cure all diseases.

Lilly made some attempts at the use of the divining rod, but failed. In the presence of many, he made an essay at night in Westminster Abbey, with a view of discovering an alleged hidden treasure; and although in one place the rods turned one over the other, nothing was found when the place was dug but a coffin. Fortunately a violent storm suddenly arose which extinguished the lights—an interruption which Lilly attributed to certain devils who had taken offence at their proceedings; but having banished these, he retreated with his terrified companions, and thus saved himself from the disgrace of failure. Although his associates in the art were generally persons of infamous character, Lilly was himself universally respected. He professed intimacy both with angels and evil spirits, and by the aid of certain prayers enlisted them in his service according to occasion.

Lilly cannot be considered as a person labouring under self-deception; he was a cunning cheat, whose impudence was of too high an order to be recognized as mere assurance, and was hence mistaken for confidence in his art. The kind of questions which he undertook to solve was, whether a certain sick person shall recover; which shall a man or his wife die first; whether a man's wife is true to him; where stolen goods are, and who is the thief; whether a king expelled his kingdom shall return or not; which army shall gain a battle; and such like. For questions about stolen goods his fee was two shillings and sixpence.

At length, in 1681, Lilly, in his 79th year, after enduring great agony, departed from the world which he had so grossly imposed upon. A black marble monument was laid, by Mr. Ashmole, over his grave in the church of Walton-on-Thames, with a Latin inscription; and two elegies were written on his death by Dr. Smalridge, afterwards Bishop of Bristol.

In execrable, and all but blasphemous rhymes, the doctor thus hyperbolically eulogises the deceased impostor. He calls him a prophet; says that he showed more light than the sun and moon together; that having viewed the "glorious train of *gilded* stars," he scorned to remain on earth; that "the *stars had so decreed*;" that the *obsequious* comet which had recently appeared came to foreshow his death; that some thought it foretold a mere plague, but that it proved the plague of plagues. He concludes by a singular metaphor. It appears there was heavy rain at the time of Lilly's death, of which he avails himself, and represents the rain as the tears of heaven falling from clouds, crying for the death of this prince of impostors. Pretty well this from a bishop that was to be.

Although in the year of the plague Lilly did some service by prescribing sudorifics, he had no medical knowledge; but in 1670 he obtained a licence to practise from Selden, Archbishop of Canterbury, by the intervention of Mr. Ashmole, who produced *a testimonial of competency from two fellows of the London College of Physicians.* He then practised extensively. His fee was generally a shilling; sometimes two shillings and sixpence; if nothing was offered, he did not ask for remuneration.

Lilly prophesied the restoration of Charles II. He represents the prophecy to have been delivered to him in signs made by angels seen in a crystal. He adds, that it is very uncommon for any operator to succeed in inducing the angels to speak distinctly; "when they do speak, *it is like the Irish, much in the throat.*"

Another distinguished *protégé* of royal favour was the renowned Dr. John Partridge, who died in 1715. A handsome monument, erected to his memory in Mortlake churchyard, bears a quaint and curt inscription in Latin to the following effect:—"John Partridge, Astrologer and Doctor of Medicine, who made physic for two kings and one queen, to wit Charles II., William III., and Queen Mary."

(To be continued.)

CASES OF AMPUTATION:

1st. Below the Knee, subsequently to the Removal of the Foot at the Tibio-Tarsal Articulation; and 2nd, at the Shoulder, during Spreading Gangrene, consequent on Disease of the Elbow joint.

THE APPLICATION OF A NEW SAW IN BOTH. WITH OBSERVATIONS.

By Richard G. H. Butcher, F.R.C.S.I.,
Examiner on Anatomy and Physiology in the Royal College of Surgeons of Ireland;
Surgeon to Mercer's Hospital,
&c. &c. &c.

(Communicated by the Author.)

(Continued from p. 105.)

The operation at the ankle-joint is no new thing. Mention has been made of it at a very remote period; it was, I think, first performed by Sedellier, and strongly advocated by Velpeau and many other French surgeons, both by antero-posterior as well as lateral flaps; but certainly to Mr. Syme is due the merit of having revived it altogether under a new aspect, by refuting the strong objections urged against it from the extent of the articulating surfaces exposed, and the scantiness of covering for the bones. The former he has lessened by the removal of the malleoli, as first practised by M. Baudens, together with the intervening cartilage; and the latter he has shown can be supplied by an efficient flap from the dense tegument and tissues of the heel. The operation was also strongly opposed on the supposition that the extensor muscles of the ankle, acting through the tendo-Achillis, when no longer antagonized, would draw up the heel, and point the cicatrix to the ground. Such a result cannot take place, Mr. Syme says, as the cut extremities of the tendons on the forepart of the joint speedily acquire new attachments, enabling them to counteract the extensive power. Well, to a certain extent this proposition maintains, perhaps sufficiently so for all practical purposes; yet I have now before me a second cast, taken from the patient Flynn, just before I operated below the knee, an interval of three months having elapsed, and during which time he was hopping about on crutches, with the leg hanging, and the stump in every movement dragged on by the powerful muscles of the calf, not only during his efforts by this mode of progression, but also while he made ineffectual attempts to walk. On contrasting it with that taken on the former occasion, the result contradicts Mr. Syme's assertion that no change takes place in the line of the cicatrix. It is here demonstrated a full half inch lower; but,

as I have before noticed, for practical purposes, this need not be taken into consideration, as it is improbable the parts on the anterior aspect of the stump would have yielded any more.

One of the advantages promised by amputation at the ankle-joint instead of the operation near the knee, according to Mr. Syme, is "a more comfortable stump will be afforded." In the case just detailed, we have evidence that the stump was perfectly formed in its most favourable proportions. The patient left the hospital with the cicatrix healed, and, as readily would have been supposed from an inspection of it, complete in every respect; yet what is the disheartening result? Why, that, after weeks of the gentlest trial, the cicatrix breaks out afresh, the limb becomes inordinately swollen, intense and burning pain fixes in the stump, occasioning restless nights and days of torture, and lastly he supplicates for its removal altogether.

The dissection of the stump reveals the causes of all his sufferings, and is extremely interesting. On lifting the indurated integuments, the subjacent layer of granular fat seemed more matted to the fibrous textures and firmer in its consistence than usual. The insertion of the tendo-Achillis was so closely applied to the plantar fascia that it presented the appearance of dividing into three dense fibrous bands, passing from behind forwards to the cicatrix. These bands, on the most convex part of the stump, were separate from each other about half an inch; the spaces between were depressed and filled with fat. On making a section of the cushion from behind forwards, exactly in the mesial line, its depth was fully three quarters of an inch, its structure fibrous, and eminently springy and elastic; this, together with the integument and fat removed, constituted a covering for the bones of an inch and a quarter thick, and formed of tissues most admirably adapted for the end in view. On examining the cicatrix, the anterior extremities of these fibrous bands, or three divisions of the plantar fascia, were fused into the cut extremities of the flexor tendons, the union between them being short and decided, and hence the improbability that the cicatrix would have descended any more by the action of the extensor muscles. On drawing aside the cut surfaces, it was quite apparent that inflammation, terminating in ulceration, had attacked the cartilage over the articulating surface of the tibia, and also the end of the fibula, from which the external malleolus was removed. The cushion was not adherent to either; it remained firmly attached, however, to the tibia, where the internal malleolus was sawn across. In addition to the increased vascularity of the bones and structures around, there was a delicate adventitious membrane, which was capable of being lifted up, spread out over the eroded cartilage; red vessels permeated and traversed it in all directions, many of them visible to the naked eye, whilst with the assistance of a lens they appeared as a complete vascular net-work. Coexisting with this condition of the interior, ulceration was also eating its way round the margin of the cartilage. The morbid appearances presented in the parts were brought on, I have no doubt, by the patient's reiterated attempts to move about; and the darting pain occasioned along the thigh, when undue pressure was made at the inner side of the cicatrix, is referrible to the bulbous condition of the nerve, for in this specimen it is very firm, and expanded to the size of a large almond. This pathological condition of the nerve, after amputation at the ankle-joint, is totally at variance with Mr. Syme's prediction when dilating on the advantages of the operation.

In the case just detailed I had no choice of site, the integuments being diseased; if I had, I should have preferred operating at the middle of the leg, or a little below it, the practice comes so strongly recommended from Charles White of Manchester, now revived and practised by Professor Fergusson of London, and so ably and forcibly urged by Dr. Laurie of Glasgow; in short, conservative surgery was never so much in the ascendancy as at present, and no man can recognize or estimate the principle more fully than I do. Yet I think it still remains to be proved that the operation at the ankle-joint affords the most comfortable and useful stump to the labouring man, and promises less risk to life. No doubt many cases are on record where the operation was performed, in some instances attended by great success. Lisfranc mentions the case of a man on whom this operation had been performed, who could walk ten or twelve miles a day with great ease, and a few similar cases are recorded by Professor Syme. In most of the published favourable cases, however, we have evidence of a prolonged confinement for the healing of the stump; but after this no reference is made to its usefulness in progression, neither have we full statistics as to the mortality attending it. I have seen the operation performed three times, and in no one case was it attended with success.

Professor Fergusson has written "On the Amputation of the Foot at the Ankle joint" in the *Medical Times* for June of this year, and speaks most favourably of the proceeding; yet he tells us:—"Whilst making these observations upon the superiority of this operation, it would not be right in me to lead you to suppose that it is invariably successful, or that it is not sometimes attended by fatal results. Of the eight patients I have operated upon, two died after it; in one of them death followed directly from the proceeding, in a few days, as it would ensue after any other amputation; great irritation and inflammation ensued, and quickly carried the patient off. In the second instance, it would not be fair to put the issue to the operation itself, as the fatal termination did not happen until several weeks after, and it was due to disease of the lungs, which had rapidly supervened after the foot had been removed." This mortality, then twenty-five per cent., I look upon as very considerable, more particularly when occurring in the hands of this distinguished surgeon. It is greatly to be regretted that Professor Fergusson did not allude, in his lecture, to the present condition of the remaining six of his cases, whether the stump in each case fulfils efficiently the object for which it was intended, and whether any of the patients solicited amputation in preference to being incumbered with a useless limb.

From my own observation, and the facts now detailed, I do not consider this operation at all so applicable to the poor labouring man as to the wealthy sufferer. The latter may at will relieve the stump from pressure, by expensive mechanical contrivance, horse and carriage exercise, &c.; whilst the former, no matter what amount of uneasiness he may experience in the part, must endure and struggle on for subsistence, and probably in the end have to submit to another operation.

Michael Scally, aged 45, by trade a carpenter, was admitted into Mercer's Hospital, June 27, 1851. For many years he has suffered from repeated attacks of inflammation of the left elbow-joint, which were variable as to their intensity and duration, but each was followed by considerable impairment of the functions of the part, and usually by marked constitutional disturbance. Twelve days before his admission to hospital, he was awoke in the night from a sensation of burning pain having fixed in the joint; neither the application of heat or cold, medicated or otherwise, would abate it, and in the morning the affected part was swollen and red, while the limb above and below participated in the discoloration and tension. There was no premonitory sickness of stomach, headache, or fever ushering in this aggravation of the local affection. He applied for relief to a practitioner, but obtained none; and after days of suffering, continuing to grow worse, he called on Dr. Macnamara, who instantly recognized the grave nature of the case, and at once recommended him to hospital. On presenting himself, he had much the look of a man labouring under far-advanced malignant disease; the expression of the face was indicative of great suffering; it was haggard and sunken, with an icteroid tinge all over it; this colour was also remarkably imparted to the sclerotics, at the same time the most striking characteristic of the eyes was their dazzling brilliancy. On being interrogated, he stated that restless nights, with unmitigated suf-

fering, and total disinclination to take food, reduced him to the condition he was then in. On examining the arm, it was swollen round the elbow-joint, four times its natural size as contrasted with the sound limb; the upper third of the forearm and the inferior third of the arm were involved in the general swelling; the integuments were of a dark red livid colour, with yellowish shading, in many places; on pressure the parts were elastic, tense and shining, while a boggy œdematous track extended along the inner side of the arm nearly to the axilla; the integuments over the deltoid muscle and outer surface of the arm were natural in colour and healthy; the constriction of the limb, down even to the fingers, was extreme. Crepitus was quite distinct in the posterior part of the joint, and the olecranon process was moveable. His pulse was small, rapid, 140 in the minute; and nothing could be more discouraging than the entire aspect of the case. After administering a full stimulant, I proposed immediate amputation of the arm, and this even in very guarded terms, as the only means affording a reasonable hope of saving his life. This proposition would not be acceded to, either by himself or his friends; so then came the question, what mode of treatment next offered the fairest promise of recovery? Amputation being rejected, as a *dernier resort* incision of the limb: yet this held out to me but little inducement to hope for success from its adoption, for the dangers from it presented under two forms, increased depression from the shock, and exhaustion and sinking from loss of blood. Still it was absolutely imperative to free the constricted parts to check the ruin going on and to arrest, if possible, the threatened death of the entire limb. Two incisions were made above the joint, and two below it; so great was the compression exerted on the parts, that the wounds, although made in the long axis of the limb, assumed almost a circular form from the extent to which they gaped. In order to lessen the amount of hæmorrhage, and at the same time effectually to relieve the tension, I adopted the following proceeding: having made the first incision, not more than an inch in length, I passed a narrow-bladed knife for an inch and a half or two inches beneath the fascia, with the surface applied to it; then turned the edge forwards, and on withdrawing the instrument, divided the fascia without cutting the integuments. A similar mode was followed in each incision.

Before he was touched with the knife, the patient mentioned forcibly the fact, that whenever he cut himself with his tools, it was almost impossible to stop the bleeding; this he experienced over and over again. In the present instance a large quantity of serum and blood followed the incisions; the hæmorrhage was troublesome at first, but was checked after some time by pieces of lint steeped in turpentine passed into the wound, well-formed compresses, and gentle pressure by the hands of assistants. After this the limb was placed in the most advantageous position on pillows, the hand being well raised, and a draught of aromatic spirit of ammonia, camphor mixture, and opium, administered. Throughout the day he was supported with wine, nutritious broth, &c., and the opiate repeated at night.

June 28th. Has had no sleep; raving at intervals through the night; pulse rapid and small; there has been no return of the bleeding; the limb, although lessened in volume on yesterday, after the escape of serum and blood, is to-day tense, engorged as before, and of a livid colour: it is extremely sensitive, so that he cannot bear the slightest touch without increase of suffering; and the inflammation, still progressive, has assumed perfectly the gangrenous character, marked by its peculiar discoloration, flaccid bullæ, &c. As one bad symptom, hiccough, had not yet supervened, I again urged the propriety of amputation, as affording, even at so remote a period, a chance of success. My colleagues, Mr. Tagert, Dr. Jameson, and Dr. Bevan, readily acceded to my proposal, and the poor sufferer most urgently wished for it now.

At eleven a.m., I proceeded to remove the limb, and adopted the circular method, for reasons to be specified presently. In consultation, it was not considered advisable to place the patient under the influence of chloroform, owing to his enfeebled condition. In a few seconds the limb was removed close to the insertion of the capsular muscles, and during this proceeding not a teaspoonful of blood was lost from above, owing to the effectual manner in which compression was made upon the subclavian artery by Dr. Jameson, while from the overloaded state of the vessels below the knife, it burst out very freely. Here no bandage could be applied to the limb before the operation, so as to anticipate and lessen this loss, owing to the aggravated suffering which the slightest pressure produced. The axillary artery was secured after it passed the tendon of the subscapular muscle, the posterior circumflex and three minor vessels were also tied; no others at the time required ligatures, or promised any trouble. I considered it the best practice to bring the cut surfaces together at once, from side to side, and retain them in position by a few points of the interrupted suture; the line of union then was vertical, and the lower part of the wound left open for some hours, to permit the escape of any oozing that might take place; the patient was placed in a comfortably heated bed, the stump well supported, and an anodyne draught with ammonia given. In a few minutes he expressed himself as quite comfortable, and free from pain. In two hours and a half after the operation bleeding began, slowly at first, drop by drop, from the inferior angle of the wound, where it was left open; dossils of lint steeped in turpentine were carefully passed in, gentle pressure applied, and the temperature of the part lowered by cold. After a few minutes it was quite apparent that this would not do; so I at once cut out the stitches, removed the adhesive straps, sponged out a few small coagula, and turned up the face of the stump to the light. No artery in particular was bleeding, but there was a general weeping from the surface; a little blood trickled from the vein, which was readily suppressed by a small piece of lint placed upon the aperture and steadied with the point of the finger for a few seconds, but the welling up from the surface still went on. All the ordinary styptics recommended in such cases were tried—turpentine, matico, strong infusion of galls, cold air, ice, &c. &c., without the least good effect; the bleeding still continued from almost every point of the divided parts. Under these circumstances, and as the man had lost a great deal of blood, I did not hesitate to apply the hot iron freely over the surface; this even only controlled the bleeding to a certain extent, for the blood still oozed out from the narrow fissures between the muscles; yet by laying fine strips of lint, soaked in turpentine, along their track, and by then applying compresses and gentle pressure, together with a bladder containing ice, over the shoulder and stump, so as to reduce the temperature of the part considerably, the hæmorrhage was at length arrested. The amount of blood lost was very great, and as a result the pulse far weaker than in the morning.

Nine p.m. The patient has been liberally supplied with wine and strong broth ever since morning; there has been no return of the bleeding; the application of ice locally, and the wine and broth, were continued, the latter even more frequently than in the early part of the day. He remained in much the same state for five hours, when hæmorrhage began slowly again. I was instantly by his side, and discovered its source from a particular fissure in the lower part of the stump; he lost about two ounces of blood before it could be arrested; this was effected after a few minutes by compresses steeped in turpentine and retained by gentle and steady pressure with the fingers. His condition now was strikingly characteristic of a man dying from repeated losses of blood; the pulse was scarcely to be felt; the respirations hurried and irregular; intellect clear; voice scarcely audible, yet the one word "air, air," was distinctly pronounced; face remarkably pallid; lips blanched; eyes brilliant; perpetual restlessness and rolling of the head upon the pillow from side to side, and gasping for breath; the hair drenched and the entire body bathed in cold sweat. In this state he continued for about half an hour after the last hæmorrhage, when he died.

The heart and large arteries were examined with great care after death, but there was nothing abnormal in their condition; there was no attempt at an internal clot in the axillary artery, yet the blood, which flowed freely in the first instance, on the earliest accession of hæmorrhage, and was received in a vessel, coagulated as firmly and as rapidly as under ordinary circumstances. On dissection of the limb, all the soft parts around the elbow-joint were in a perfectly gangrenous condition; the investing capsule of the joint in front was entirely destroyed, and the periosteum was stripped from the lower third of the humerus and the upper third of the radius and ulna. The articulating surfaces of the three bones were entirely denuded of cartilage, and in several places deeply eaten away by ulceration. In many points there was proof of repair being set up at an earlier period, and as if nature struggled hard to effect a cure; for over the articulating surfaces on each bone there were patches of smooth, porcelain-like deposit; the lateral ligaments were destroyed, and the annular ligament of the radius yielded in front. There was a perfect solution of continuity between the olecranon process and the ulna, corresponding to the transverse sulcus lodging the fatty bodies (Haversian glands) within the joint. It is true the fragments were kept partially in contact by the expansion of the triceps muscle reflected from one to the other, yet the coaptation was not so perfect as to prevent motion between the opposed surfaces, and the crepitus so strikingly elicited during life.

The foregoing case is a well-marked instance of the hæmorrhagic diathesis; in its management the most trifling points were weighed to guard against loss of blood. I should have preferred removing the limb at the shoulder-joint, by a flap operation, and I am convinced it was the most applicable proceeding, when taking into account the diseased condition of the soft parts in the neighbourhood of the axilla; yet I readily abandoned it, on estimating the cut surfaces to be greater, consequently the liability to bleeding more than by the circular method.

The case just detailed illustrates well the advantages of the saw represented in the woodcut. The bone had to be divided very high up, and certainly no saw could be passed under the soft parts with a like facility in this situation; the fine narrow blade allowed of this adaptation, and the bone was cut in a perfect curve—a procedure that should be adopted in every case; by it the sharp edges of the bone are removed, which, when left, are a constant inciter to pain and spasm, permitting the soft parts to lie more evenly in contact in the bottom of the wound, and thus facilitating adhesion.

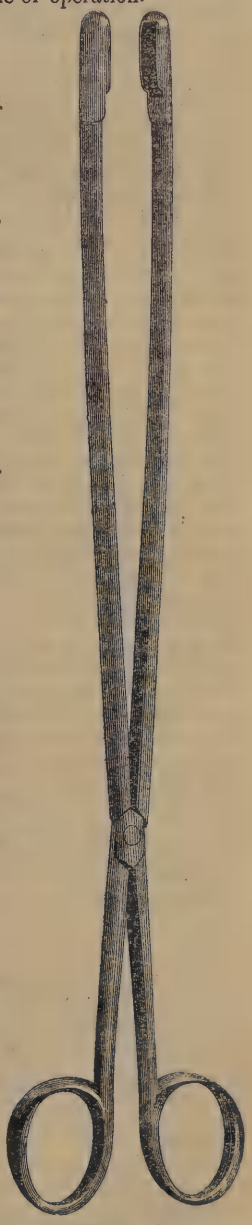
THE CHOLERA.—By the latest intelligence from the West India Islands, dated July 17, we are informed that the cholera was still prevalent. The most distressing accounts are from the parishes of Hanover and Westmoreland, in Jamaica. The medical practitioners were exerting themselves to stay the plague, but as yet their efforts had not proved successful. The pestilence had also broken out among the military stationed at Up Park Camp, and several of the soldiers had died. Every precaution had been taken to prevent communication between the citizens of Kingston and the inhabitants of the adjacent districts with the soldiers' encampments. Tents had been erected, and the affected soldiers placed within them; and every other caution taken to prevent, as much as possible, the spread of the disease. Up to the 5th of July, there had been buried from Savannah-la-Mar, in the cholera-ground, 115; from Dunbar's River and the neighbourhood, 45; and on the 6th there were six burials, making a total of 166; besides which, four new cases were reported on the following day, and the hospitals were full. Mr. Davidson, the assiduous superintendent of the hospital is among the victims. Accounts from Manchioneal announce the reappearance of cholera in the district of St. Thomas in the East. The cases, however, appear to have been principally, if not exclusively, among persons who have fled from the Plaintain-Garden River district on the reappearance of cholera there. One of these was the case of a man who had been working at Golden Grove, and died at Windsor Forest the morning after he arrived there from the former property.

DESCRIPTION OF A NEW FORCEPS FOR THE REMOVAL OF UTERINE POLYPI, BY THE COMBINED INFLUENCE OF PRESSURE AND CAUSTIC.

By M. M. O'GRADY, M.D., M.R.I.A., Malahide.

(Communicated by the Author.)

THE difficulties which have occurred to me, in common with the most experienced practitioners, in operating with the instruments ordinarily employed for the extirpation of uterine polypi, induced me to turn my attention to the construction of a forceps by which the operation might be simplified and effectually performed without the necessity of confining the patient to bed, or of exposing her to the risk of being injured by the presence of the double canula in the vagina during the time the ligature takes to cut through the pedicle; or to any of the other disagreeable consequences attending this mode of operation.



Having operated seven times successfully with the instrument hereafter described, without causing the least pain, and without the patients losing a drop of blood during or subsequently to the performance of the operation, I am induced to lay a description of it before the profession; I will also add a brief account of two cases, which suggested to me the idea of its construction, and of combining mechanical pressure with the action of nitrate of silver upon these morbid growths. The instrument was made under my immediate directions by Thompson and Co. of Henry-street.

The entire length of the forceps is ten inches, and that of the blades, measuring from the pivot to the extremities, five inches and a half, each blade terminating in a semitubular chamber, of about half an inch in length, closed and rounded at the extremity, and open on the inner surface, so as to form a groove for the reception of a piece of caustic.* Both these chambers having been charged, and the forceps shut, the caustic is completely enclosed; it is thus introduced into the vagina or os uteri with perfect safety. When the blades are separated for the purpose of seizing the object to be operated upon, the caustic can come in contact only with the substance grasped by the forceps. Its action then is twofold. First, the edges of the caustic chambers break down the vessels of the polypus by compression; and secondly, the caustic decomposes its substance with great rapidity. The forceps is withdrawn as soon as all resistance to its pressure appears to have yielded, and the parts are then washed out with a solution of the carbonate or hydrio-

* I had the portion of the instrument in which the caustic was included made of silver. Platinum or gold would of course answer better; but Dr. Carte suggested to me that a coating of gutta percha would be as effectual, and, I need not say, very much cheaper.

date of potash, which decomposes the caustic and prevents its acting on the os or cervix uteri. The patients, with the precautions usually adopted, may safely be permitted to walk or drive out, as if no operation had been performed; and at his next visit the operator will find the polypus loose in the vagina, if not already discharged into the night-chair.

The following are the cases to which I have already referred:—

Case 1.—On the 10th of September, 1848, I was sent for in a hurry to see Mrs. W., aged 39. She was pale and faint from loss of blood. Upon examination, there was a large fleshy mass protruding between the labia pudendi; it bled freely from many points of the exposed surface, and on introducing the finger I found that the tumour passed through the os uteri, and nearly filled the vagina. She could not have lost less than twenty ounces of blood during the last twenty-four hours. She was the mother of six children, and had a bad miscarriage about two years before; she had suffered from vaginal discharge since then, and occasionally lost considerable quantities of blood at the regular monthly periods.

Not being prepared for the nature of the case, I had neither speculum nor ligature, and being obliged to act at once to arrest the hæmorrhage, it occurred to me to apply to the bleeding surface the nitrate of silver, which I always carry about me, having been in the habit, for at least twenty years, of using it extensively in inflammation of the throat and fauces, and latterly in ulceration of the os and cervix uteri. I was surprised at the rapidity of its action upon the polypus, which it reduced for at least one inch to a black carbonaceous mass. It arrested the hæmorrhage instantaneously, and enabled me to leave my patient in a state of security in less than an hour, cautioning her at the same time to send for me if there was the least return of the bleeding. On the day following I found this lady cheerful and in excellent spirits, although naturally weak from the loss of blood. There had been no return of the hæmorrhage since I left her. I now introduced Fergusson's speculum, which the polypus filled. Having this shade for the vagina, and encouraged by the result of the application of the caustic made the day before, I destroyed another portion of the polypus in a very short time. Still apprehending a return of hæmorrhage, I used the precaution of plugging the passage, but I found this at my next visit to have been wholly unnecessary, inasmuch as not a single drop of blood had been lost. In a week the polypus was destroyed up to the os uteri, which, being in a healthy state, closed upon the remainder.

I mentioned to this lady that the polypus was not entirely extirpated, and that it was likely to be reproduced, and told her, in the event of the recurrence of the symptoms, to send for me. I did not hear from her again until the 14th March, 1849, when I was again summoned to see her. I found her suffering much from bearing-down pain, which she had for the last week, and upon introducing the speculum a polypus was seen, about two inches long, issuing from the os. Having, in the meantime, operated upon another patient with the forceps I have described, I had no difficulty in securing and destroying this polypus within the cervix, from which it grew. The entire operation did not last five minutes, and the lady dined with her family that day. She has since had one child, and has continued to enjoy the best health.

Case 2.—In February, 1849, I was consulted by Mrs. M., aged 58. She married young, is the mother of ten children, and had several miscarriages. I attended her in four confinements, the last fifteen years ago. Her general health was always good until the age of 56 or 57, when she had leucorrhœa and pain in her back, with bearing-down upon taking exercise. For the last three months the discharge has been more profuse and high-coloured, and for two or three days back she bled freely from the vagina. She is now pale, nervous, and very much alarmed about herself. Upon examination, I found a fleshy mass in the vagina, which bled freely from one point. I introduced Fergusson's speculum, by which a polypus at least four inches long, and issuing from the os uteri, was revealed. Having found the nitrate of silver in Mrs. W.'s case so efficient, I applied it freely to this polypus, and with the like happy result; the bleeding ceased at once, and never during the subsequent treatment returned.

Having succeeded in destroying a great portion of the polypus by the caustic, I repeated the application the next day. The forceps, now rudely finished, and charged with caustic, came to my assistance. With it I seized the remainder of this polypus, at its origin in the cervix, from which it grew, and with great rapidity broke it down and reduced it to a black carbonaceous pulp; no blood was lost in any stage of the operation.

As my object in narrating these cases is to introduce this forceps, and the mode of operating with it, to the notice of the profession, I will merely remark, that I removed two more polypi of a similar character from this lady, all of which grew from the interior of the cervix uteri, the last in September, 1850, and that I saw her yesterday, July 16, 1851, in as good health and spirits as ever she enjoyed. She assured me that she has not suffered the slightest inconvenience or return of any of the symptoms since the last operation.

SEVERE GUNSHOT WOUND—LIGATURE OF THE SUBCLAVIAN ARTERY.

One of the most interesting cases of recovery from a severe gunshot wound, occurred lately at the naval station of Bassadore, in the Persian Gulf. While the H. C. Brigantine Tigris was lying there in the month of February last, one of her midshipmen, Mr. Fendal, had proceeded on shore for a day's shooting; and most unhappily when in the act of drawing it towards him by the muzzle, his gun accidentally exploded, and its contents lodged in his left shoulder. As the muzzle was at the time within a few inches of his breast, the injury sustained was of the most frightful character. The upper part of the arm was nearly blown from the body, the bone badly broken, and the pellets of shot driven in about the shoulder and front of the chest. The loss of blood that ensued was so profuse that in a few minutes he sank exhausted, and in this fainting state was carried to the nearest house. It unfortunately happened at the time that there was no surgeon attached to the vessel: however, the hospital assistant succeeded, by application of tourniquets and bandages, in stopping the flow of blood. In this state of matters, Lieutenant Manners, who was commanding, despatched his vessel across to the Arabian coast, where he knew the steam-frigate Auckland, carrying the only surgeon there attached to the Gulf squadron, was at that time cruizing; and by a very fortunate hit, fell in with that ship at the hour of midnight, as she was proceeding on her voyage from Sharjee to Bahrein. The assistant-surgeon in charge, Mr. Crawford, was aroused from his bed, despatched at once on board the Tigris, and was carried with all alacrity to Bassadore, where the wounded midshipman still lay. Upon arrival at the scene of suffering, he immediately proceeded to a careful examination of the wound, and, having concluded that amputation at the shoulder joint was inadmissible, he adopted such measures as appeared to him necessary for the preservation of life. Matters for the first fortnight were progressing favourably, and his exertions were encouraged by the improving state of the patient, when unhappily secondary hæmorrhage of the most violent character set in. The first bleeding took place about two o'clock in the morning, but luckily Mr. Crawford slept in the house, and being upon the spot, adopted such measures as soon stopped the flow of blood. In a few days the patient was again going on well, when exactly one week from the first bleeding, a second, much more profuse, and threatening death in a few seconds, occurred at midnight. The gush of blood was temporarily arrested, but Mr. Crawford found that it proceeded from an injury to the axillary artery near the collar bone, and that the only hope of preserving the life of the patient was

to perform the operation of tying the subclavian artery as it runs under that bone. Although without assistance, Mr. Crawford proceeded at once to the operation, and succeeded in a few minutes in achieving his object. By the administration of suitable restoratives, and a steady course of judicious treatment, the patient gradually revived, and everything connected with the operation succeeded so favourably, that after the expiration of five or six weeks his health and strength were almost reëstablished. Shortly after this accident the Tigris was ordered upon some pressing duty, so that Mr. Crawford was left in charge of his patient, without the society of any other European at the station, and during this interval he was forced to undertake another rather severe operation upon the bones of the wounded arm, by which he hoped to preserve that member; and now not only is the sufferer restored to strength again, but the wound is nearly well, and there is much hope that the arm will still be a very useful one. The operation of tying the subclavian artery is but of modern date in surgery, and was for the first time attempted by Ramsden, at Bartholomew's Hospital, in 1809; the patient died five days after the operation. Afterwards by Sir W. Blizard, Dupuytren, Colles, Sir A. Cooper, and other eminent surgeons; the patients all dying about the fourth day after operation. The first successful case occurred in the hands of Dr. Post of New York, in the year 1817, and the next instance was in 1820, when Mr. Liston was the operator. Since then there have been occasional rare cases, but those of a favourable termination enumerated by surgical writers form but a small number, and it is therefore a source of much pleasure to us to be able to add one to the list from the presidency of Bombay. We believe, moreover, that this is the first case of the kind that has happened in India; and when we consider that the operation was performed at midnight, the patient in a most inconvenient position, upon a bed from which he dared not be moved, and without the aid or advice of a professional brother, we can have little hesitation in pronouncing the result to be most creditable to the operator.—*Bombay Journal.*

INDICATIONS AFFORDED BY THE PULSE IN CARDIAC DISEASES.

By R. B. Todd, M.D., F.R.S.

After some introductory observations on the importance of the *tactus eruditus*, in studying the pulse, Dr. Todd speaks of the character of

The Pulse in Heart Disease.—I shall first direct your attention to those varieties of pulse which are characteristic of heart disease. The most prominent and well-marked form of pulse in heart disease is one which I described to you in my last lecture as the *locomotive* pulse: it consists essentially of a sensible, as well as visible, throbbing pulsation of all the arteries throughout the body, seen, of course, most conspicuously where the arteries are most superficial, and also where they are most curved. The increased conspicuousness of the movement at the flexures of the arteries depends upon its being really greater there—upon its being not only a change of calibre, as in situations where the artery is straight, but a change in the position and relations of the whole artery. This movement of the whole artery I conceive to be thus produced. The natural inclination of the moving fluid is, of course, like all moving matter, to continue its motion in a straight line; but in a serpentine artery the course of the blood must also be serpentine; and how is this change of direction to be imparted to it? Manifestly by the walls of the artery, and especially by that portion of the walls which constitutes the convex border of the curvature: on this side is thrown the whole of the stress of the impulse, and the effect, therefore, is to throw the artery, or to elongate it, in that direction. In a serpentine artery, the convexity of the curvatures is alternately on opposite sides, and therefore the impulse of the blood, and the movement it gives rise to, is thrown alternately on opposite sides; hence not only the greater movement, but the increased length of curved arteries, and the vermicular character of their motion, is accounted for.

But to return. When you place your finger on a locomotive pulse, you may perceive, by attentive examination, that the peculiar state of pulse is dependent, not only on a remarkable fulness of the artery, but also on a remarkable collapse; that the systolic distension is suddenly followed by a considerable diastolic contraction. The excessive fulness of the artery is, however, merely apparent, and not real; it appears excessive by contrast with the unusual degree and suddenness of the collapse which preceded it, and which follows it; the blood is impelled into an artery not at all filled to tension, and the succeeding collapse takes place suddenly, instead of by a more gradual subsidence. Now, auscultation and anatomy teach us that this character of the pulse is due to regurgitation. When the ventricular contraction which injects blood into the arterial system has ceased, the stress on the arterial walls is at once relieved by the reflux or regurgitation of a portion of the blood into the ventricle; and as this regurgitation is not gradual, but instantaneous, the collapse is equally so, which is so immediately followed by a fresh injection of blood, expanding the artery, and giving rise to the jerking character that the pulse possesses.

Let us suppose that three ounces of blood are thrown out of the ventricle at each systole, and that immediately afterwards one of these three ounces regurgitates through the patent aortic valves, imagine what a disturbance such a state of things must necessarily occasion in the circulation through the heart, and what a deviation it must be from the natural condition of an artery, filled to tension, firmly supported behind, and gradually relieved in front by the onward capillary movement. This state of pulse, when well developed, is always indicative of regurgitation through the aortic valves; I know of no condition of pulse which exactly imitates it; that which comes nearest to it is what is seen in some cases of low disease, as typhus or rheumatic fever of a low kind, as I mentioned to you in my last lecture; or an atonic state of the arterial system, with dilatation of the large trunks, and a yielding condition of the aortic valves. In this case the heart propels the blood into the artery with little tone; the result is that the artery becomes fully and suddenly disturbed by the impetus; there is therefore great enlargement and consequently great collapse, the collapse being perhaps favoured by a yielding condition of the valves: this is the only imitation of it that I know. Now, you will always be able to ascertain the true cause of this locomotive condition of the pulse by examining the heart itself; if it is dependent on a weak and yielding state of the arterial walls, *you will hear the natural second sound, but feeble;* if, on the other hand, it is dependent on valvular lesion, you will hear, instead of the normal second sound, a bellows-sound, generated by the regurgitation of the blood through the patulous aortic valves, and called, from its being synchronous with the diastole, a "diastolic bellows-sound."

You have at the present time a good opportunity of making yourselves acquainted with this form of bellows-sound, as well as with the locomotive pulse accompanying it, in the case of John Loveland, a patient in the Sutherland Ward, to whose case I have before referred. Let me here narrate to you some of the characteristics of such a state of disease, with the history and phases of which it is highly important you should be familiar. The patient is aged 24, and seems to have been exposed to much hard walking, as well as hard work. He appears to have suffered from some acute affection about three months previous to his admission, but what the exact nature of that affection was does not clearly appear; it seems partly to have partaken of the character of pleurisy, and partly of pericarditis, perhaps of both. From this, however, he in a measure recovered; and when in a state of convalescence, walked seven hundred and twenty miles, at the rate of twelve or fifteen miles a day. The fact was, he belonged to a club which pays its members when out of work a shilling a day and a penny a mile for every mile they walk in search of work. It was on this search that he tramped from town to town, when he ought to have been in his bed; and to this, in a great measure, is to be attributed his present condition. Under this constant exercise, his cardiac symptoms increased very much, and he was admitted into the hospital the latter end of last February. His symptoms were then, and still are, dyspnœa, constant, but exacerbated by anything that increases the rapidity of his circulation; cough, of a peculiar, spasmodic, and dry character, not terminated by expectoration, but ending in retching, and sometimes in vomiting. There is nothing elicited by the physical examination of the lungs to explain this cough and dyspnœa; but on examining the heart, the area of dulness marking the portion of it in contact with the thoracic parietes is found to be greatly extended. Those of you who are now

listening to heart-sounds for the first time, I advise to listen to the heart of a neighbouring patient, with the heart healthy; you will then hear what the natural sounds are, and will be able to appreciate the aberrations from them: you will hear the prolonged first sound, and the short click of the second. Then turn to Loveland, and in place of this clicking second sound, you will hear a soft blowing murmur—a bruit de soufflet, or bellows-sound. The first sound, too, is not natural, but partakes of the same character; and if you transfer the stethoscope from the base to the apex of the heart, you will hear this bellows-murmur as distinct as the other: you will have a regular see-saw—what is specifically called a "double bellows-sound." The murmur that *supplants* the second sound has its seat at the aortic valves; that which *accompanies* the first sound is seated at the mitral valve; and both are dependent on regurgitation at these respective situations. Judge, then, what must be the embarrassment that results from the double regurgitation—this two-fold counter-current through orifices that ought to be closed.

In the present case, the existence of mitral regurgitation renders the locomotive character of the pulse less marked than usual; for all the blood in the ventricle is not impelled into the artery, but a part of it passes back into the auricle: there is less distension of the artery, and consequently its collapse less marked. A locomotive pulse, such as you have in Loveland, is as bad a sign as a patient with heart disease can have. The form of derangement of which it is indicative is most dangerous, because it is a derangement that more than any other interferes with the proper circulation through the heart. Hence it is that in cases of this kind we meet with so much dyspnœa. Dropsy has already begun to appear; the right side of his heart is becoming dilated, and it will get so more and more; and you will find that in eight or ten days, if the patient should live so long, his dropsy will be considerably increased, and his other symptoms will have acquired greater prominence.

A second variety of pulse which you are likely to meet with in heart-disease is a *small weak* pulse, which accompanies mitral disease, whether regurgitant or obstructive. The effect of either condition of the mitral orifice—whether it be the patulous condition, allowing regurgitation or a contracted state, obstructing the flow of blood into the ventricle—is necessarily to diminish the quantity of blood to be expelled by the ventricle. The arterial system is, therefore, imperfectly supplied with blood, and consequently not distended; so that a full pulse cannot be formed. When mitral disease of either kind coexists with a weak state of heart, then the character of weakness and smallness of pulse will be enhanced in proportion to the degree of mitral disease and of debility of heart. It is this character of pulse, and this state of valvular disease, that we often find accompanied by a weak and sometimes a dilated ventricle, intermission of pulse, and, still more frequently, a great irregularity in the rhythm of the pulse; two or three beats succeeding each other at a rapid rate, then a few slow beats, then rapid ones again, and so on. You may likewise have this form of pulse in cases of obstructed aortic orifice, accompanied by a weak heart, in which the obstruction is so great as to permit only a small stream to emerge from the heart; and you may have it in cases of simple weakness of heart.

A third form of pulse which accompanies heart-disease, while it may be more or less full, is especially characterized by a *thrill*, which accompanies the impulse, imparting to the finger a peculiar vibrating sensation, as if the blood were rushing past certain obstacles with considerable rapidity and force. This is indicative of obstructive disease situated at the mouth of the aorta, or in its first portion. A warty growth from the valves projecting into the mouth of the aorta may give rise to this form of pulse by obstructing and dividing the stream, and creating secondary currents, which are the immediate cause of the thrill. In such cases you always have an aortic systolic bellows-murmur of a rough kind—the *fremissement cataire* of the French—which is audible along the large vessels of the neck, and frequently in all the larger arteries; and sometimes, and not unfrequently, this murmur will have a peculiar musical character, dependent on similar vibrations to those which cause the thrill.

We also meet with a *throbbing* and *full* pulse, which strikes the finger with considerable force, in cases of hypertrophy of the heart, which are not complicated with valvular derangement. The bounding character of the pulse resembles the action of the heart itself. There is another point relative to the pulse in hypertrophy of the heart, which has been noticed by Dr. Graves, and is worthy of your attention—namely, that the *frequency* of the pulse is not altered by position. He states that in six cases of hypertrophy with dilatation of the heart, no difference was produced in the frequency of the pulse by change of posture. I suspect this must have been due to much the same cause as the same phenomenon in cases of weak heart, to which I alluded in my last lecture; for the heart with hypertrophy and dilatation, although acting strongly and with considerable, because extended, impulse, is yet, no doubt, weak in relation to what it has to do—that is, to the obstacles which it has to overcome.

I have already told you, in a former lecture, that an *intermittent* pulse is not in general indicative of any particular disease of the heart, that it is most frequently the result of merely functional disturbance; but in cases where you have any reason to apprehend an inflammatory state of heart, such as rheumatic fever, an intermitting supervening upon a previously regular state of the pulse, is a most significant symptom: it indicates almost with certainty the first accession of pericarditis or of endocarditis. After a very short time, however—sometimes only a few hours—the pulse will become regular, even in the most confirmed endocardial or pericardial inflammations. Under these circumstances, you may have a pulse more or less full, but not in general strong. Sometimes, however, if the endocarditis cause imperfection of the mitral valve, as it very often does, the pulse may assume the small and weak character which it is apt to exhibit in mitral regurgitant disease.*—*Med. Gaz.*

DIAGNOSTIC VALUE OF PAINS IN THE HEAD.

By David Nelson, M.D.

An organic pain will be fixed, and always aggravated under exertion, or any other stimulant, to the circulation; and may depend either on acute hyperæmia or passive congestion, or any of their results, from a solid clot to a simple effusion of serum. In the event of acute action, the pain will be of a darting character, with much heat of the scalp, fiery sensitive eyes, and great watchfulness, and will require abstraction of blood, mercurial purgation, and the application of cold. In passive congestion, or in effusion, the pain will be dull and heavy, with perhaps some heat of the scalp, but the eyes will be darkly suffused, the general frame less sensitive of external agents, and the sufferer will rather be inclined to drowsiness. The pain may further be of a rheumatic nature, depending on some especial determination of irritating urinary salts which may be retained in the circulation; this is to be inferred from the general history of the patient's constitution, from the presence of contemporaneous pains in the joints, and from the state of the urine. If confined to the external parts, as it commonly is, it will readily be removed by the ordinary remedies for rheumatism, but if it involve the brain itself, or its membranes, it is likely to prove as fatal and irresistible as other affections of that organ are known to be. The headache that proceeds from derangement of the stomach or bowels is commonly called a sympathetic one, arising from the immediate nervous connexions that exist between the abdominal viscera, and especially the stomach and brain. At its first onset it will certainly be subdued in exact correspondence with the success which attends your treatment of the digestives, whether such treatment be directed to the neutralization of acid, or oils, or the simple expulsion of any other irritating matter, or to the removal of hyperæmia. But it will certainly sometimes continue long after the stomach and bowels have been brought back to a tolerably healthy state of action, especially when the previous complaint happens to have been of very long standing.

This is especially illustrated in the hydrocephalus which supervenes as a secondary effect on the abdominal affections of young children, though it may perhaps be doubted whether the functions of any organ can ever be perfectly renewed after any protracted attack of inflammation, however mild. Another sort of headache is consequent upon very long fasting, or watchfulness, or mental effort, or any other cause of nervous exhaustion, and this of course can only be removed by nutrients and rest, aided by some stimulant, as very well instanced in the headache which succeeds a debauch, or excessive grief. I have already spoken of the heat of the scalp, of the appearances of the eye, and of the nature of the pain, as illustrative of the different forms of hyperæmia which

* I have great pleasure in referring to some excellent remarks on the pulse in heart-disease in the valuable series of "Lectures on Cardiac Diseases," by my friend Dr. Bellingham, lately published in the *Medical Gazette*.

may be suspected, but may also add that the condition of the tongue has a close connexion with such a state of things. Along with the bilious sympathetic headache, and that of congestion, we have a tongue thickly furred with white or brownish yellow; emetics are advisable for the first, but not for the second, if much straining be anticipated. In the nervous headache, and that which is concomitant with affections of the lesser bowels and colon, it is almost always clean, but entirely red; but as alteration of structure advances, the fur again returns, at first of a simple white, next a yellow, afterwards brown, and lastly a deep dry black. In the headache that accompanies certain enlargements and other affections of the liver, the tongue will be found of a bright pink colour, moist, and of a glassy smoothness, either in whole or in part; or, on the other hand, it will be deeply fissured transversely.—*Prov. Med. Jr.*

THE MEDICAL CHARITIES' BILL.

AN ACT

TO PROVIDE FOR THE BETTER DISTRIBUTION, SUPPORT, AND MANAGEMENT OF MEDICAL CHARITIES IN IRELAND; AND TO AMEND AN ACT OF THE ELEVENTH YEAR OF HER MAJESTY, TO PROVIDE FOR THE EXECUTION OF THE LAWS FOR THE RELIEF OF THE POOR IN IRELAND.

(7th August, 1851.)

10 & 11 Vict. c. 90.

WHEREAS it is expedient to provide for the better distribution, support, and management of certain of the medical charities in *Ireland*, and to amend for this purpose the provisions of an act passed in the eleventh year of her present Majesty, intituled *An Act to provide for the Execution of the Laws for Relief of the Poor in Ireland:* be it enacted by the Queen's most excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present parliament assembled, and by the authority of the same.

Appointment of Commissioners to act with Poor-law Commissioners.

1. That it shall and may be lawful for her Majesty the Queen, by warrant under her sign manual, from time to time to appoint two persons (one of whom shall be a physician or surgeon of not less than ten years standing, and shall have the title of Medical Commissioner,) who, together with the commissioners appointed under the provisions of the aforesaid act of the eleventh year of her Majesty, shall, from the time of the publication hereinafter directed to be made in the *Dublin Gazette*, be the "Commissioners for administering the Laws for Relief of the Poor in *Ireland*," within the meaning of the aforesaid act, pursuant to, and with the powers and authorities given by, the said act, and the several acts for the more effectual relief of the destitute poor, and also for executing this act, and such two persons so appointed under this act shall hold office during the pleasure of her said Majesty; and immediately on the publication aforesaid the office of assistant commissioner created by the said first-mentioned act shall cease and determine; and in the absence of the chief commissioner for the time being in the said act mentioned the powers, duties, and functions of the said chief commissioner under the said act shall be exercised by such one of the other commissioners as shall be appointed so to act by a majority of the commissioners, with the approval of the Lord Lieutenant of *Ireland*.

Appointment of Commissioners to be published in *Gazette*. Powers given by this Act how to be exercised.

2. Notice of the appointment of such two persons by her Majesty shall be published in the *Dublin Gazette*, and on the day after the publication of the first appointment of such persons all the powers and authorities given by this act to the said commissioners for administering the laws for relief of the poor in *Ireland* shall take effect, and shall be exercised by them, in like manner as the powers and authorities given to the commissioners appointed under the said act of the eleventh year of her present Majesty: provided always, that any order for the formation or alteration of any dispensary district or districts under this act, as hereinafter mentioned, or for framing or establishing any general rules or regulations relating thereto, or altering or revoking the same, shall be signed by not less than two of the said commissioners.

Appointment of Inspectors.

3. The said commissioners may from time to time appoint so many fit persons as the commissioners of her Majesty's Treasury shall sanction, being practising physicians or surgeons of not less than seven years standing, to be inspectors to assist in carrying out the provisions of this act, and may remove all or any of the said inspectors, and appoint others in their place.

Salaries of Commissioners and Inspectors to be paid from any Funds provided by Parliament for such Purpose.

4. There shall be paid to the said two commissioners to be appointed under the provisions of this act, and also to the said inspectors, such salaries as shall be from time to time appointed by the Commissioners of her Majesty's Treasury, out of any monies which may from time to time be provided by parliament for that purpose.

No Medical Commissioner or Inspector to practise as Physician or Surgeon.

5. Neither the medical commissioner nor any such inspector as aforesaid shall, while he continues in such respective office, practise as a physician or surgeon, or in any other professional capacity.

Power to Guardians to divide Unions into Dispensary Districts.

6. The guardians of each union in *Ireland* shall, when so required by the said commissioners for administering the laws for relief of the poor in *Ireland*, with all reasonable despatch, divide such union into so many dispensary districts, having regard to the extent and population of such districts, as may to them appear necessary; and in case the said commissioners shall approve of the districts so formed by the said guardians, they shall issue an order under their seal declaring the same; and in case they shall not approve of the districts so formed by the said guardians, the said commissioners may and they are hereby empowered to issue an order under their seal declaring the districts which to them may appear necessary; and it shall be lawful for the said commissioners, and they are hereby empowered, when they may see occasion, from time to time to require the guardians to alter such districts, subject to the approval by order under seal of the said commissioners, and in case of their disapproval, or of the neglect of the guardian to make such alteration when required, the said commissioners may alter such districts by such an order; provided always, that in no case shall an electoral division formed under the acts for the more effectual relief of the destitute poor be divided; and from and after a day or days to be named in any such order the cost of all medical relief afforded within any such dispensary district to which such order shall relate, together with all the salaries and charges incidental to the same, shall be charged on the poor-rates of the electoral division or divisions comprised therein, according to the net annual value of each such division under the poor-law valuation in force for the time being; and the said commissioners shall declare in such order the number and qualifications of the officers to be appointed for the service of each such dispensary district, and shall likewise declare in the said order the number of persons who shall be members of the committee of management of such districts, as hereinafter is provided.

Appointment of Dispensary Committee.

7. Within one month after the receipt of the said order the guardians of the union shall elect, if necessary, a sufficient number of ratepayers resident in each district, and liable to pay poor-rates in respect of property therein of the net annual value of thirty pounds at least, who, together with the *ex-officio* and elected guardians of the poor resident or being the owners or occupiers of property therein, shall be a committee for the management of

the dispensary of such district, so that the number of the members of the said committee shall amount to the number named in the order of the said commissioners, and shall from time to time fill up any vacancies occurring after any general election of such committee; and the committee so appointed shall hold office until the appointment of a new committee after the next annual election of guardians in the said union; and at the first meeting of the guardians after such annual election, or as soon thereafter as conveniently may be, the committee of management for the said dispensary district shall be appointed in like manner for the ensuing year, and so likewise in each succeeding year.

Guardians to provide Offices for Meetings, &c., and also Medicines, &c. Committee of Management, with Approval of Commissioners, may appoint Officers, and with such Salaries as the Guardians, with the like Approval, may determine.

8. The guardians of the union shall, as soon after receipt of the said order as conveniently may be, provide a house, building, room or rooms, to be used as a dispensary or office for the medical officer of each such district, and for the meetings of the committee of management, and shall provide such medicines and medical appliances as may be necessary for the medical relief of the poor in the said district, and the committee of management shall appoint, from time to time, subject to the approval of the said commissioners, one or more medical officers for the said district, with such qualifications as the said commissioners shall determine, and with such salaries as the guardians, subject to the approval of the said commissioners, shall determine; and the said commissioners may, and they are hereby empowered when they may see occasion, from time to time to regulate the amount of salaries or allowances payable to such officers respectively, and the time and mode of payment thereof; and it shall be lawful for the said commissioners to remove any such medical officer on sufficient grounds, and to direct the said committee of management to appoint another medical officer in his stead; and, on failure of the said committee to appoint a medical officer of such dispensary district for one month after the receipt of the direction of the said commissioners, it shall be lawful for the said commissioners to appoint such medical officer by an order under their seal.

Power to afford Dispensary Relief.

9. Every member of such dispensary committee, and every relieving officer and warden acting for an electoral division included in such dispensary district, shall have power to afford medical relief by the issue of a ticket for medicine and advice, or a ticket, in such form as the said commissioners shall prescribe, addressed to the medical officer of the district, directing him to afford medicine and advice to or attend any poor person resident therein; and it shall be the duty of the medical officer to afford medicine and advice, or to attend such poor person, as thereby directed: Provided always, that if any person who shall obtain a ticket for medical attendance from any relieving officer or warden, or from any member of the committee, shall, at the next or any subsequent meeting of the committee after the issue of the ticket, be declared by a majority of the members then present not to be a fit object for dispensary relief, the ticket shall be cancelled, and the holder thereof disentitled to further relief.

Other Provision made for Dispensary Relief to cease after Day named in Order of Commissioners. Proviso as to County Infirmaries, &c., under 5 G. 3, c. 20. (I.)

10. From and after the day to be named as aforesaid in the order of the said commissioners declaring any dispensary district, all provision now made by law for affording dispensary relief from poor rate, or by means of presentment from the county cess, shall, except for the purpose of defraying expenses incurred before such date, cease as to the baronies or portions of baronies or places included in such dispensary districts, and all funds and property derived or arising for the support of such institutions from bequests shall be applied to the support thereof according to the trusts on which such bequests were granted: Provided always, that where, under the provisions of an act of the parliament of *Ireland* passed in the fifth year of his late Majesty King *George* the Third, intituled *An Act for erecting and establishing public Infirmaries and Hospitals in this Kingdom*, any allowance or stipend is now payable to any officer of a county infirmary or other medical institution, such respective allowance or stipend shall wholly cease to be payable to or to the use of such infirmary or medical institution under the provisions of the said act, when and as soon as the person holding such office at the time of the passing of this act shall wholly cease to hold the said office in the said infirmary or medical institution: Provided also, that nothing herein contained shall be construed to deprive of the benefit of aid from any parliamentary grant any infirmary or hospital in the city or county of *Dublin* now receiving such aid, so long as such aid shall continue to be granted by parliament.

Members of Committee of Dispensary not to be concerned in supplying Articles for Use in Dispensary, under penalty of £50 and costs.

11. No guardian or member of the committee of management, paid officer, or other person concerned in the providing, ordering, management, control, or direction of the medical relief of the poor in any dispensary district, shall, either in his own name or in the name of any other person, provide, furnish, or supply for his own profit any medicines, instruments, furniture, or goods for the use of any dispensary in any district for which he shall act in any such capacity as aforesaid, during the time for which he shall retain such office, nor shall during such time be interested, directly or indirectly, in any contract relating thereto, under pain of forfeiting the sum of fifty pounds, with the full costs of suit, to any person who shall sue for the same by action of debt or on the case in any of her Majesty's courts of record at *Dublin*.

Regulations as to Management of Dispensaries.

12. The said commissioners shall and may, and they are hereby directed, with all reasonable despatch after the first appointment of commissioners under the provisions of this act, to frame general rules and regulations for the government of each dispensary district, and for the guidance and control of the guardians, the committees of management, and the several officers to be appointed in connexion therewith respectively, and shall be empowered to alter or revoke such rules and regulations, and make such new rules and regulations, from time to time, as they may think fit.

Regulations as to Vaccination. 3 & 4 Vict. c. 29.

13. The medical officer of every dispensary district constituted under this act shall and he is hereby required to vaccinate all persons who may come to him for that purpose, subject to such regulations as may be issued by the commissioners in that behalf, and which regulations the said commissioners are hereby required to make and issue; and that from and after the declaration of any such dispensary district it shall not be obligatory on the board of guardians of the poor-law union containing such district or any part thereof to make a contract with a medical practitioner for the vaccination of persons resident in such district, under the provisions of an act passed in the fourth year of the reign of her present Majesty, intituled *An Act to extend the Practice of Vaccination*: and after the appointment of a medical officer for such dispensary district all existing contracts theretofore made with the guardians under the authority of the last-mentioned act shall cease and determine, payment being made to such medical practitioner of such proportional sum for past services as may then be due to him.

As to existing Medical Officers of Dispensaries.

14. When, on the formation of any district under the provisions of this act, a medical practitioner shall be in possession of a medical office connected with any dispensary subject to the authority of the said commissioners, and situate in the locality included in such district, it shall be lawful for the commissioners, if they shall think fit, to declare him to be, in the first instance, the medical officer

or one of the medical officers of such new district; and so likewise when two or more medical practitioners shall be circumstanced as aforesaid, in case the like number of medical officers is required in such new district, it shall be lawful for the said commissioners, if they shall think fit, to declare such persons to be the medical officers of such new district; but in case a smaller number of such officers shall be required for such district, then it shall be lawful for the said commissioners, if they shall see fit, to nominate such persons, or any of them, as the persons from whom a selection shall be made for a medical officer or officers under the provisions of this act, by the parties entitled to appoint to such office; and it shall not be necessary for the said commissioners, unless they think fit, to reject any such medical practitioner so in possession of any such office before the formation of such district, by reason of the want of such qualifications as may be required by them in other cases.

Salaried Medical Officers of Districts to attend at Examination of dangerous Lunatics, and to give Attendance at Bridewells within their Districts.

15. It shall be the duty of any salaried medical officer of a dispensary district under this act, or (if more than one) then the nearest of such medical officers, save in the case of his sickness or necessary absence, and then the other nearest of such medical officers, without any further fee or reward, to examine and certify under the statute in that behalf as to the case of any dangerous lunatic brought before a justice of the peace, within his respective district, when summoned by such justice so to do, and also to give his medical attendance and care, so far as shall be necessary, to the prisoners or inmates in any bridewell or house of correction situate within such respective district, and to supply to such prisoners and inmates the necessary medicines, the account of which medicines shall be submitted to the next meeting of the committee of such respective district, who shall make provision for the payment thereof; and it shall be lawful for the said commissioners, if they shall think fit, to take into account the probable extent of such extraordinary duties with respect to any such bridewell or house of correction, in fixing the amount of the salaries of the medical officers of such districts.

Power of Commissioners and Inspectors to inquire on Oath, or require a Declaration. Provisions as to the summoning of Witnesses, &c., by Commissioners and Inspectors.

16. The commissioners or any one of them, and also any such inspector acting in execution of this act, by summons under the seal of the commissioners, or under the separate hand and seal of any commissioner or inspector respectively, as the case may be, may require the attendance of all such persons as they or he shall think fit to call before them or any of them respectively upon any matter connected with the execution of this act, relating to any dispensary subject under this act to the authority of the said commissioners, at such time and place as shall be set forth in the summons, and may make inquiry and require returns, and may administer oaths, and examine all such persons upon oath, and may require and enforce the production upon oath of books, contracts, agreements, accounts, maps, plans, surveys, valuations, and writings, and copies thereof respectively, in anywise relating to any such matter as aforesaid; or when the commissioners, or any one of the commissioners, or any inspector, shall think fit, instead of requiring such oath as aforesaid, they or he may require any such person to make and subscribe a declaration of the truth of the matter respecting which he shall have been or shall be so examined: provided always, that no person shall be required, in obedience to any such summons of any of the said commissioners, to go more than thirty statute miles from the place of his abode, or, in obedience to any such summons of an inspector, to go more than five miles from the place of his abode: provided also, that nothing herein contained shall empower the commissioners or any commissioner or inspector to require the production of the title, or of any papers or deeds relating to the title, of any lands, tenements, or hereditaments, not being property under the authority of or vested in the said commissioners by this act: provided also, that nothing herein contained shall authorize the said commissioners or any of them, or any such inspector, to exercise such powers of summons, inquiry, examination, or other such last-mentioned powers as aforesaid, in the case of any hospital, infirmary, or medical institution supported by private endowments, bequests, property, or subscriptions.

Penalty for giving false Evidence. Penalty for refusing to attend to Summonses or to give Evidence.

17. Every person who upon any such examination as aforesaid under the authority of this act shall wilfully give false evidence, or wilfully make or subscribe a false declaration, shall be deemed guilty of a misdemeanor; and every person who shall refuse or wilfully neglect to attend in obedience to any such summons as aforesaid of the commissioners, or any one of the commissioners, or any inspector, or to give evidence as aforesaid, or shall wilfully alter, suppress, conceal, destroy, or refuse to produce any books, contracts, agreements, accounts, maps, plans, surveys, valuations, or writings, or copies of the same, which may be required as aforesaid to be produced for the purposes of this act, to any person authorized by this act to require the production thereof, shall be liable to forfeit a sum not exceeding five pounds, to be recovered before any justice or justices at petty sessions under his or their warrant, by distress and sale of the goods of the party so offending, returning to such party the overplus.

Inspectors to visit Dispensaries and attend Meetings of Guardians, &c. Commissioners and Inspectors to inspect and report upon Hospitals, &c., supported by public Funds, Rates, &c.

18. Every inspector acting in execution of this act shall be entitled to enter at all times into and to inspect every dispensary or building used for the purposes of this act, and to attend the meetings of every board of guardians or dispensary committee, on all business arising in the execution of this act, and to take part in the proceedings, but not to vote at such meeting; and the said commissioners, or an inspector by their order in writing, shall be empowered (when they shall deem it expedient) to enter, inspect and report upon any infirmary, hospital, or medical institution supported in the whole or in part by any public funds, rates, or assessments.

Commissioners to execute in Ireland the Nuisances Removal and Diseases Prevention Act, 1848, (11 & 12 Vict. c. 123), and the amending Act (12 & 13 Vict. c. 111).

19. The said commissioners shall be the commissioners for executing in *Ireland* the powers and purposes of "The Nuisances Removal and Diseases Prevention Act, 1848," and an act of the following session of parliament amending the same; and all committees, inspectors, medical officers, and other persons appointed or employed under the powers of this act shall and they are hereby required, within their respective districts, to aid the guardians of the poor, and such officers or persons as they shall appoint or employ, in the superintendence and execution of any directions and regulations which may at any time be issued by the said commissioners for the time being under the authority and by virtue of the said Nuisances Removal and Diseases Prevention Act and the said act, amending the same, or under or by virtue of the provisions hereof in relation thereto; and all expenses which shall be incurred on account or in execution of the said last-mentioned act or acts, and chargeable upon the poor-rates, shall hereafter be charged on the poor-rates of the respective electoral division situate within such district, in like manner, and be ascertained, paid, and audited, in all respects as directed for the expenditure under the provisions and for the purposes of this act.

Annual Reports to be made to Lord Lieutenant, and laid before Parliament.

20. The said commissioners shall once at least in every year submit to the Lord Lieutenant a general report of their proceedings under the provisions of this act, including

the total expenses incurred in *Ireland* and in each union in carrying this act into execution in each year, together with a list of all districts and dispensaries under this act, and the total annual expense of each; and every such general report shall be laid before both houses of parliament on or before the thirty-first day of *March* in each year, if parliament be then sitting, or if parliament be not then sitting, within six weeks after the next meeting of parliament.

Interpretation of Terms.

21. In the interpretation of this act the words "Lord Lieutenant" shall extend to and include the Chief Governor or Governors of *Ireland* for the time being, and the word "medical" shall be construed to extend to and include the word "surgical" unless there be something in the subject repugnant to such construction.

Commencement of Act.

22. This act shall commence and take effect from and after the first day of *October* one thousand eight hundred and fifty-one.

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, AUGUST 20, 1851.

THE NEW DISPENSARIES ACT.

The Dispensary Surgeons of Ireland are at length relieved from the distressing state of doubt and suspense in which they have been kept for nearly fifteen years, and they have now inevitable certainties only to contend with; to which they must apply themselves calmly and firmly. To indulge in retrospective contemplations, or complaints of past proceedings, will prove but a waste of valuable time and energy which present exigencies demand. It matters little who were the authors or promoters of this measure, or what may have been their motives; it is now accomplished, and it only remains for those liable to be affected by it to watch and direct its operation; not in a spirit of hostility, or with a feeling that they have to encounter aggression and injustice, but with a conviction that those who are to execute the provisions of this act will see the necessity of adopting a policy having for its object the association of the medical profession with the department of the executive government entrusted with the care of the poor. Doubtless, much difficulty will be experienced in the endeavour to attain harmonious coöperation between parties heretofore frequently in collision; but let not hereafter the blame of miscarriage be laid on the medical profession, should the arrangements adopted lead to such a result. We counsel not any such line of conduct as a servile acquiescence in the views of official people, should such views be manifestly opposed to a liberal provision for the relief of the sick poor; what we advise is a frank tender of coöperation by our profession, should a distinct understanding be come to, on the one part, to do what is just and liberal; on the other, to ask nothing unreasonable or impracticable. Allowances must be made for the difficulties of the case, and the inevitable sacrifices which must of necessity attend the execution of the act; while every consideration must be given to claims which may be considered of the nature of vested interests. That some of the existing Dispensaries must be extinguished by the operation of this act cannot be doubted (the number it is impossible even to guess at); but that the surgeons of these suppressed institutions should have the first claim for appointment elsewhere cannot be questioned. Here, however, one of the first difficulties to be encountered will arise. The Committee of the new District Dispensary, the Guardians, or the Commissioners, may see good cause for a departure from this rule, and even deserving men may be set aside, but that a very large majority of the present surgeons will retain their appointments seems certain. It may be cold comfort to those liable to be discontinued to say so, but in some situations, we believe, there are dispensaries so badly supported, and so unworthy of a surgeon's attention, that their suppression must prove beneficial even to the persons who cling to them as an only resource. In fact, we are of opinion that there are many, very many, members of our profession in Ireland who will be saved from a life of poverty and inaction by a compulsory removal. Be this, however, as it may, we are convinced that there is no reason to despond. Matters, we fear, have come to such a pass that worse they cannot well be in some cases, and in most cases a change cannot be looked to with much apprehension. It is scarcely necessary to say, that the success of this measure will mainly depend upon the choice made by the Government of the Medical Member of the Poor-Law Board. We do not wish to say much on the subject, lest we should stumble on some observation liable to be construed into a hint favourable to some one of the numerous candidates for the office. We may, however, say this much. Let not the new Commissioner be a person despised by our profession: if not in all respects unexceptionable for the duty, we pray that he may be a person of *respectable* character. If he should not be a man of transcendent integrity, let him not be one who glories in his exploits in the art of chicanery. If a certain amount of courtly deference to his superiors be a necessary qualification in him, we advise that he be not a cringing and fulsome parasite; and if a proper independent bearing becomes his position, let us not have in lieu of it an offensive and obtrusive familiarity: above all things, we hope that he may have some character for veracity. These negative qualities may appear to some unworthy of specification; but looking as we do to the realities around us, we are content with them; being satisfied that the situation is not one which should be thrown as a reward to a political adherent, or as a provision for a personal *attaché*, irrespective of ability to discharge the duty or to win the confidence of the parties concerned.

MEDICAL REFORM.

THE LONDON APOTHECARIES' COMPANY.

The following somewhat amusing occurrence suggests inquiries which we have not now leisure to make. The cordial fraternization of the Censors of the College of Physicians with the Worshipful Company is significant; and the virtuous indignation displayed touching the homœopaths and their economical globules is instructive. That all parties are moved by a most virtuous anxiety to labour *pro bono publico* there can, we believe, be no question; but still there appears a latent suspicion that some sceptics begin to think that people may have too much physic as well as too little:—

The Society of Apothecaries.—On Wednesday, the 30th ult., this society sat down to an excellent dinner, provided by Mr. Quarterman, at the Crown and Sceptre, Greenwich, the Master, M. L. Este, Esq., in the chair, supported on the right and left by the censors of the College of Physicians, Dr. Wilson and Dr. Crawford, and Sir Charles Forbes, Dr. Taylor, and several distinguished foreigners. The number present, including visitors, amounted to 160. After grace had been said, the Master gave, as the first toast, "the Queen and the Royal Family," which was responded

to with the utmost loyalty, cordiality, and enthusiasm. What might, however, be considered the event of the evening, in a professional point of view, originated in the next toast, given in a neat and appropriate speech by the Master—viz., "the College of Physicians," coupling with it the name of the son of his old and highly respected teacher, Dr. Wilson. Dr. Wilson, in reply, said—"Excellent Master and gentlemen, in the absence of Drs. Paris and Monro, both of whom much regret that they were unable to be here, in consequence of the *soirée* given this evening by the College of Physicians to the distinguished foreigners at present in London, it becomes my duty to respond to that toast. The allusions to my late father remind me that it is now nearly twenty-five years (a quarter of a century) since I last had the honour of forming one of your party, and during that period what extraordinary changes have taken place: railroads, telegraphs, and a thousand other additions, have been made to the comforts and conveniences of life; but to me the most gratifying change—and one of which you may justly be proud, and which has been effected principally by your exertions—is the manifest advance which has taken place in the scientific attainments and moral status of the medical profession of the present day. And here let me ask, has the public appreciation of that status kept pace with its improvement? Has it not rather retrograded? We certainly had then some charlatans: I can scarcely recollect whether St. John Long was then in existence; but what have we now? Have we not quackery rampant, as in homœopathy, now reduced to a regular system, appealing to and supported by the credulity of a *soi-disant* enlightened public, and publishing as its patrons the names of individuals in elevated positions, from whom better things might have been expected. When I last had the honour of addressing you I was junior censor; I am now senior censor, and I avail myself of this, the first opportunity which has occurred to me, of denouncing the whole system as a vile and wicked imposture, alike repugnant to the principles of honour, honesty, and truth, as to the well-established facts of medical experience. From the various reforms which have been effected, and are now in progress, it matters little whether a man add M.D., M.R.C.S., or other initials to his name; it behoves one and all regularly educated practitioners to unite in 'a long pull, a strong pull, and a pull altogether,' in putting down a system fraught with mischief to the interests of the community at large, no less than to the individual members of the profession. It behoves us, I say, to bear in mind, that at no distant period the elections may come, and it may then be our duty to evince to the world that the highly respectable portion of the community to which we belong, can have little confidence in individuals as legislators who manifest such a total absence of common sense, and so vast an amount of gullibility and credulity, as to patronize so wicked a system of humbug and imposture." The other usual toasts having been given, the company broke up at an early hour.

PRACTICAL HOMŒOPATHY.

We need not enter into further particulars of the charge we made against Mr. Kingdon than to publish two of his recent prescriptions, *verbatim et literatim*. It will be seen that they are both recent, and they were both given to the same patient, for the same malady, within seven days of each other:

℞ Belladon. (3rd Dil.) gl. vj.
Sacchar. Lactis. Gxii.
M. intime et Divid.
in chart iv. quar.
j nocte maneque v.
W. K. Chir.

Mr. —— June 7, 1851.

From Headlands,
Princes St.
Hanover Square.
℞ Decoct. Cinchon. ℥vss.
Sp: Ammon. arom.
Tinct. Cinchon. c.
āā ℥ij.
M. 6tam part ter quotid.
s.
℞ Hydrarg. c creta Giij.
Confect. Opiat. Gix.
M. intime et Divid.
in pil iij quar j o, n,
s.
W. K. Chir.

Mr. —— June 14, 1851.

These prescriptions afford evidence, not only of Mr. Kingdon's perversion to globulism, but of a far worse state of things. We have before now received assurances that the globulists whenever they fall into any difficulty forsake their shams and resort to the real resources of regular physic. Here is, as it appears, a speaking instance of it. On the 7th of June, Mr. Kingdon orders his patient globules of infinitesimal sugar and belladonna, made into powders; on the 14th of June, Mr. Kingdon prescribes full doses of bark and mercurial, just one week after his homœopathic trash. Can anything be more treasonable or bad, in everything relating to faith and morality, on the part of a medical practitioner? The only other explanation which the case admits of is, that Mr. Kingdon, being sent for as a regular medical man, and receiving payment as such, did nevertheless impose the globules upon his patient, without his patient's knowledge. But this supposition is, if possible, more damaging than the first.—*Lancet.*

MEDICAL CHARITIES' BILL FUND.

The Treasurer, Dr. Morrison, acknowledges the receipt of £1 from Dr. McCrea, Clondalkin Dispensary.
Newry, Aug. 9, 1851.

MEDICAL BENEVOLENT FUND.

The Treasurer acknowledges the receipt of 10*s.* from Dr. Cavet of Waterford, and one guinea from Dr. Clayton of Athy.

EXPLOSION OF YEAST.

On Thursday, July 24, Mr. H. M. Wakley held an inquest at the Bank of England public-house, Praed-street, Paddington, on James Parfett, aged 35, a porter at the Paddington terminus of the Great Western Railway, who was killed under the following extraordinary circumstances:—Mr. George Strange, clerk in the goods department of the station, stated that at nine o'clock on Tuesday morning he saw the deceased returning from breakfast along the platform, where lay several casks of yeast which had arrived from Oxford. Just as he passed the casks one of them, containing eighteen gallons, suddenly burst with a loud explosion, blowing the cask thirty feet into the air, together with the deceased, who was struck under the chin by a corner of the cask. Deceased fell on his back six yards from the spot where the explosion took place. Witness instantly ran to the spot, where he found deceased apparently dead, and bleeding from large wounds under his jaw and on the top of his head. He had him conveyed to St. Mary's Hospital, where he died half an hour after his admission. The barrels appeared to have been very badly hooped. Just before the fatal occurrence, witness observing the yeast escape from the cask, feared an explosion would ensue, as on other occasions yeast barrels had exploded. On one occasion he nearly lost his life thereby. He did not consider the barrels safely secured. Mr. Superintendent Collard of the railway station, said that the yeast belonged to Mr. North of Oxford, and that he never before heard of such an accident. There was a clause in the company's act which compelled them to convey gunpowder and all combustible material by a separate train, but the company never considered that yeast came within the meaning of the clause. After the examination of several other witnesses, the jury returned a verdict that "Deceased was killed by the accidental explosion of yeast."

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

REPORT ON IRREGULAR PRACTICE.

The following Report was brought up and unanimously agreed to:—

Brighton, 14th August, 1851.

Your Committee have, after consultation with numerous Members of the Association, maturely considered the subject referred to them, and beg respectfully to suggest the adoption of the following Resolutions:

1. That it is the opinion of this Association, that Homœopathy as propounded by Hahnemann and practised by his followers is so utterly opposed to science and common sense, as well as so completely at variance with the experience of the Medical Profession, that it ought to be in no way or degree practised or countenanced by any regularly educated medical practitioner.

2. That Homœopathic practitioners, through the press, the platform, and the pulpit, have endeavoured to heap contempt upon the practice of Medicine and Surgery as followed by members of this Association and by the profession at large.

3. That for these reasons it is derogatory to the honour of members of this Association to hold any kind of professional intercourse with Homœopathic practitioners.

4. That there are three classes of practitioners who ought not to be Members of this Association, viz.,—1st, real Homœopathic Practitioners; 2nd, those who practise Homœopathy in combination with other systems of treatment; and 3rd, those who under various pretences meet in consultation, or hold professional intercourse with those who practise Homœopathy.

5. That a Committee of seven be appointed to frame laws in accordance with these Resolutions, to be submitted to the next annual meeting of the Association.

6. That the thanks of the Association are eminently due and are hereby given to the Presidents and Fellows of the Royal Colleges of Physicians and Surgeons of Edinburgh for their determined stand against Homœopathic delusions and impostures.

7. That the thanks of the Association are also due and are hereby given to the Universities of Edinburgh and St Andrew's for their resolution to refuse their diplomas to practitioners of Homœopathy; but the Association feels imperatively called on to express its disapproval of any School of Medicine which retains among its teachers any one who holds Homœopathic opinions.

8. That these Resolutions be printed, and transmitted to all the Medical Licensing Bodies and Medical Schools in the United Kingdom; and that they likewise be inserted in the *Times* newspaper, the *Morning Post*, the *North British Advertiser*, *Saunders' News-letter*, all the British and Irish Medical Periodicals, and in such other Journals as the Council may sanction upon the recommendation of the Branch Associations.

In proposing these Resolutions for the adoption of the Association, your Committee are anxious to state that they are actuated by a strong sense of the importance of the subject in its relation both to humanity and morals. They most conscientiously believe that the countenance afforded to the form of charlatanry herein alluded to is detrimental to the true interests of the public, as it is subversive of that strict integrity which ought to characterise practitioners of Medicine, and which has ever distinguished the profession in these Kingdoms.

John Rose Cormack, M.D., Edin.,
Fellow Royal Coll. Phys. Edin. (of Putney.)
James Tunstall, M.D., Edin. (of Bath.)
H. H. Ranking, M.D., Cantab. (of Norwich.)

It was moved by Dr. Malden of Worcester, and seconded by Dr. Charles J. B. Williams of London, that this Report be adopted.

The motion was put from the chair and unanimously agreed to.

The following Committee were then appointed in terms of the fifth Resolution:—Dr. Cormack of Putney, Dr. Tunstall of Bath, Dr. Ranking of Norwich, Dr. Malden of Worcester, Sir Charles Hastings, M.D., of Worcester, and Dr. Cowan of Reading. Dr. Cormack to be Convener.

On the motion of Dr. Tunstall, it was unanimously resolved that the proceedings in reference to this subject be printed and circulated among the Members.

G. S. Jenks, President.
J. P. Sheppard, Secretary.

Pavilion, Brighton, August 15, 1851.

DISPENSING OF MEDICINE.

G. OLDHAM and CO.,
Pharmaceutical Chemists, and Apothecaries,
From Bewley and Evans',
No. 107, Grafton-street, Dublin,
(Corner of Suffolk-street),

Beg to return their grateful acknowledgments to the Medical Profession for the support they have hitherto received, and which they will regard as a fresh motive for exertion. Abstaining altogether from visiting as Apothecaries, except for the application of Leeches, Cupping, and such operations as are performed under medical advice, they will continue to devote themselves exclusively to the duties devolving on the pure Pharmacien.

Having had much experience in Practical Pharmacy, and being resolved to spare neither trouble nor expense in order to have every article of superior quality, they hope by attention, "carefulness," punctuality, and moderation of charges, to commend themselves to the approbation of those who may entrust them with their commands.

☞ *G. O. and Co. invite attention to their present stock of Surgical Instruments, all of which are manufactured on the most modern and improved principles.*

Printed by Thomas Dees, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, Arthur Jacob, M.D., 23, Ely-place, in the city of Dublin.

HISTORICAL SKETCH OF THE CONNEXION OF ASTROLOGY WITH MEDICINE.

By M. Donovan, Esq., M.R.I.A.

(Continued from p. 116.)

The influence which astrologers exercised on the actions of individuals and the policy of states is truly surprising: the greatest and the smallest movements were directed by them. When the caliph Almanzor had resolved to remove the seat of government from Damascus, he would not determine on a site for the new city without their advice. A pleasant meadow on the eastern bank of the Tigris was chosen, and there, A.D. 767, was founded the city of Bagdad. (Addison.) In the present day, the court astrologer of the Ottoman empire directs the time for taking every important step relative to the affairs of the nation. No Osmanli ever undertakes a journey, builds a house, marries a wife, or commences any business of importance, without a determination from the astrologers of the auspicious hour. Should misfortunes accumulate about him, instead of attributing them to worldly causes, he ascribes them to his constellation. When he is sick, he procures from the priest an earthen bowl inscribed on the interior with passages from the Koran, and filling it with water, sets it aside until the writing is effaced, when he swallows this dose of what he considers holy writ. (Miss Pardoe: City of the Sultan.) The Caucasians will scarcely undertake any important enterprize when the horoscope is clouded with gloomy forebodings. The various changes of the moon and the aspect of the stars are also consulted. (Spencer: Travels in Caucasus.) At Lahore, "Runjeet Sing told the commander-in-chief that the planets would not be propitious to the marching of the troops on the 27th of March, and he consequently hoped we would defer our departure till the following day, which they had fixed on as being more so. The general was obliged to do this." (Fane: Five Years in India, 1842.) Sir J. Malcolm, in his History of Persia, states that a Persian ambassador was compelled by his astrologer to throw down several high walls to enable him to quit the town without facing an invisible constellation which would have marred his good fortune. (Mignan: Winter Journey, &c.)

Frederick II., Emperor of Germany, having married Isabella, sister of Henry III. of England, he refused to consummate his marriage until the astrologers appointed the fitting moment: notwithstanding which precaution his queen died in childbirth. Having occasion to quit Vicenza, he would not do so until the astrologers declared what gate he should pass through; nor would he leave Padua with his troops until directed by the astrolabe what hour he should march; and when he determined to build the city of Vittoria, he should have the advice of the astrologers as to the fittest time—an advice which deceived him not a little, as the new city was shortly after destroyed. (Tiraboschi.)

In a letter from Petrarch to Boccacio, it is stated that when Galeazza Visconti intended to besiege Pavia, the marching of the troops which had been already ordered was countermanded by the astrologers, who said that it was proper to abide the time forefixed by heaven. The day arrived; the march commenced, and such torrents of rain fell that the plains were inundated.

The great mind of Henry IV. of France was not superior to the influence of this absurd superstition. For a long time he deferred the coronation of his consort on account of a prediction that he would not survive that ceremony a single day: the assassin, Francis Ravaillac, perhaps instigated by the prophecy, fulfilled it, May 14, 1610. The unbending Wallenstein was led like a child in leading strings by his astrologer Seni, who read in the stars the future success of his master. (Schiller.) At the court of Catherine de Medici nothing of any consequence was done without reference to the astrologers. Guido da Montefeltro, Lord of Farli, had so much reliance on Guido Bonatti, already mentioned, that he would not venture on giving battle but at the hour dictated by him. One of the persons sent over to Norway, and entrusted with bringing home "the Maid of Norway" on the death of her grand-

father, Alexander III., in 1283, so much depending on her succession to the throne, was Sir Michael Scott, the celebrated astrologer and necromancer already mentioned, notwithstanding which the maiden died on the passage.

Filippo-Maria Visconti, Duke of Milan, was superstitious beyond all comparison, and a devoted believer in astrology, so much so, that during conjunctions and oppositions of the planets, the public business was suspended, and he buried himself in total privacy. He caused gold medals to be struck, bearing astrological characters, which he believed efficacious against the destructive effects of lightning. Against thunder he contrived a double wall. On Fridays he dreaded to meet any one that was not shaved; and on any day would not eat his dinner if the servant who placed the covers made the first step with the wrong foot. (Pietro Candido Decembrio, in Muratori: Sketches of Venetian History, ii., 62.)

One of the duties of the astrologer was to calculate nativities. This was done by ascertaining the position of the heavens at the moment of the birth of the native, as the person was technically called, concerning whom the inquiry was made. On this position depended the future fortunes of that person.

The dangers sustained by the Roman empire from the attempted fulfilment of the prophecies of soothsayers and astrologers rendered the calculation of the nativity, or inquiry into the horoscope of the reigning sovereign, an offence liable to the severest punishments. During the reign of Tiberius, Furius Scribonianus had consulted the astrologers relative to the period of the emperor's death, and for this he was exiled. Augustus interdicted the astrologers from predicting anything relative to the death of any person, either privately or publicly, although he, on his own account, was so little anxious that he had proclaimed publicly the aspect of the stars under which he was born. (Dionis Hist. Rom., lib. 56.)

In the reign of Edward IV., Mr. Thomas Burdett, a gentleman of rank and fortune, was executed in the Tower of London for conspiring with a clergyman named Stacey, to calculate the nativity of the king and his son. Lord Hungerford was beheaded for seeking information as to the duration of the life of Henry VIII. One of the charges against the Earl of Bothwell was his having consulted relative to the duration of the life of King James. A celebrated astrologer named Gadbury, being importuned to calculate the nativity of Charles II., well knowing the danger, not only refused the task but gave information against his instigator; the Duke of Buckingham had been already sent to the Tower because, amongst other crimes, he had influenced an astrologer to commit that offence. One of the physicians of Louis XIV. was charged with having possession of the king's horoscope; to which he pleaded in his defence, that it was his duty to possess an instrument so intimately connected with the king's health and life.

During the seventeenth century astrology was degraded in the hands of the lowest impostors, who lent their aid to every villany, and sold charms and philtres, having a base object in view. The great plague which broke out (1664 and 1665) in London, opened a vast field for the speculation of impious wretches, whom not even the manifestation of this awful chastisement from the Almighty could deter from braving the dangers of the afflicted capital; nor could the appalling red cross on the houses of the infected, with the solemn inscription, "Lord, have mercy on us," remind them of the fearful judgment which might fall on them the next hour.

The character of astrology did not in England long survive Lilly. Dr. William Ramsay, who lived about the same time, and a little after, made an effort to continue it in favour by the publication of a book called "Astrology Restored," but it failed in its object. He professed to foretel a man's fate, particularly whether he should be rich, or fortunate in marriage, and predicted good luck to himself in both instances; but he got a bad wife, and died a pauper in a prison. By the word astrology he means the influence of the stars which cause diseases; and this he calls the pure astrology of Hippocrates and Galen, without a knowledge of which he accounts a physician and a fool to be synonyma. He insists on the necessity of a knowledge of astronomy for the physician, as leading to astrology. Ramsay was a man of some learning; he was the last of the learned astrologers of Britain, as Gassendi and his antagonist Morin were on the continent. The former died in 1655, the latter in 1656.

A contemporary of the last days of the astrologers (Mr. Chambers) thus sums up his estimate of the race:—He says that they are confederates of the devil; that they are all damned, and deserve to have their bones broken.

Amongst the astrologers, as has been shown, there were men of great erudition; but there was also a class of impostors whose chief characteristics were unblushing impudence and destitution of all principle. About the year 1633, several of these *practised* in London, and we have the following accounts of them.

Alexander Hart, formerly a soldier, now professed questionary astrology and physic. He was chiefly employed in predicting for young gentlemen addicted to gambling the fortunate hours when they would win at dice. A curious citizen of London, being anxious for a conference with a ghost, agreed to pay Hart thirty pounds for calling up one. The ghost, however, disobeyed, did not appear, and thus abandoned the seer to his chance of the pillory, which he escaped by flying to Holland.

Dr. Jeffry Neve, who obtained his medical degree in the Low Countries, was also a student in astrology; he died in 1651, and in his will left the following considerate and pious item:—"If Dr. Ardee (a friend of his) give my wife anything that is mine, I wish the devil may fetch him body and soul." This Dr. Ardee, physician and astrologer, seems to have been under especial tutelage. He declared that an angel had once appeared to him, and offered him a lease of his life for one thousand years. He had a friend, one Charles Sledd, an apothecary, who used the crystal, and could commune with spirits which he could summon to appear in it.

Dr. Nicholas Fiske practised physic and astrology at Colchester, and afterwards in London; he could resolve horary questions very soundly; and was exquisitely skilful in the art of directions upon nativities. He directed Sir R. Holborn's nativity.

The Reverend William Breden, vicar of Thornton, in Buckinghamshire, was a profound divine, and the most polite person for nativities in that age, strictly adhering to Ptolemy. But unfortunately the reverend gentleman was so much addicted to drunkenness and smoking, that when he could not procure tobacco he used to cut the bell ropes and smoke them. There were some other characters of equal respectability practising the science of the stars. (William Lilly.)

The dreadful tragedy enacted during the reign of James I. is worthy of a passing notice, on account of the parts enacted in it by a doctor and an apothecary. Dr. Simon Forman, an astrologer, had been imprisoned by the London College of Physicians (1592) for professing to distinguish and cure diseases by ephemerides, heavenly signs, and aspects, without the aid of medicine. (Goodall's Hist. of Coll. of Physicians.) William Lilly gives the following account of him:—"This physician studied astrology in Holland (1580); he was a person that in horary questions (especially thefts) was very judicious and fortunate; so also in sicknesses, which indeed was his masterpiece. In resolving questions about marriages he had good success; in other questions very moderate." He had set a figure to discover his fortunes, and from it predicted that before two years he should be a lord; but he confesses that within the time specified he found himself a prisoner in Newgate instead of being a lord. This was at the prosecution of the college. In one of his manuscript books is the following interesting notice, which shows that he

could not avoid cheating even himself:—"This I made the devil write with his own hand in Lambeth Fields, 1596." He foretold that he should die on the next Thursday, and so he did, although in good health up to that day. (Life of Lilly.)

Such was the chief agent in the poisoning of Sir Thomas Overbury in the Tower of London; the following are the circumstances recorded in history. The Countess of Essex made use of persons who professed sorcery and witchcraft to ensnare the affections of Lord Rochester, the handsomest man of his day, for whom she had conceived an illicit passion. Philtres and the usual detestable practices of the art were employed, and the lady's passion was ultimately responded to. Sir Thomas Overbury, who at first had assisted Rochester in the intrigue, perceiving that the design of the countess was to espouse Rochester after she had obtained a divorce from Essex, sought to defeat her by his influence over Rochester. The latter having induced King James to send Overbury to the Tower, the countess determined to remove this obstacle to her happiness; she therefore employed the notorious Mrs. Turner, a brothel-keeper and reputed sorceress, to aid in her scheme. The countess had already consulted this woman as to the best means of making away with her husband Essex. Turner, willing to oblige her patroness in both ways, called to her assistance Dr. Forman and his friend an apothecary, named Franklin; both used their skill in compounding various slow poisons, which were mixed in the food of the unfortunate captive, day after day, by his keeper, Weston, who received twenty pounds for his services. They consisted of aqua fortis, arsenic, lunar caustic, and cantharides; but being too slow for the impetuous desires of the countess, the poor victim was despatched by a good dose of corrosive sublimate. Forman was the prescriber of the poisons compounded by the apothecary. He appears to have had no great skill as a poisoner, although he professed that art along with medicine, fortune-telling, astrology, sorcery, and magic. Such was the detestation of Turner's crime, and the interest manifested in her execution, that persons of high rank of both sexes attended in their carriages at Tyburn. (State Trials. Miss Aickin; and all the historians of the time.)

We have seen that from very early ages astrology constituted an essential part of medicine, and continued to be so down to times not very long past. The faculty of Paris, in the hope of checking its spread, had condemned it as a diabolical and dangerous art. In the sixteenth century, philosophers, moralists, and satirists contributed their efforts to dissipate the delusion: we find Gesner, Erasmus, Picus of Mirandola, and others, engaged in the contest. The poets contributed their aid, amongst whom Butler stood foremost. Even Ariosto could not refuse himself the pleasure of a passing sneer. He says that when Astolfo visited the moon, he found there a quantity of sense that belonged to various persons on earth; amongst the rest, that of the astrologers, corked up in bottles, it being subtile, and apt to exhale:—

"Di sofisti, e d'astrologhi raccolto
E di poeti ancor ve n'era molto." (Orlando Fur.)

The insinuation being, that if the common sense of the astrologers was bottled up in the moon it could not be in their brains. The following practical jeer is related of William Duke of Mantua. The birth of a foal being expected on a certain night, the duke caused an astrologer to sit up and watch in the stable. The foal was born, its horoscope was cast by the astrologer, but it was published as if it were that of the duke's natural son. The obsequious astrologers of the time administered the proper quantity of adulation in prophetic anticipations; they discovered in the horoscope that the supposed offspring of the duke was to be something great—a celebrated person, a puissant warrior; some determined that he was to be a cardinal; others made him pope. The duke, amidst this diversity of opinion, disclosed the trick he had played, to the utter scandal of the astrologers. (Encyclop. Metrop.)

In Alexandria a tax was imposed on astrologers and astrological seekers called Βλκαενομιμον, under the supposition that the ridicule attached to the name of the impost would act as a restriction.

St. Ambrose thus ridicules astrological predictions. If a child be born under the sign Aries, he shall be wise in council and rich, because the ram is the leader of his flock, and because every year he produces a rich fleece; if the child be born under Taurus, he shall be strong and laborious, because the bull submits his neck to the yoke; if born under Leo, he shall be fierce like the lion; if under Scorpio, he shall be malicious and poisonous like the scorpion; if under Pisces, he shall be silent as a fish. (Gaule.)

Such was the kind of science which had long disfigured the knowledge of physicians. Diseases were placed under the influence of the twelve signs of the Zodiac; planetary influences were believed to cause some diseases, while they cured others: all medicinal herbs were affirmed to be under the dominion of some planet or other; and the aspect of the planets determined the treatment to be adopted by the physician. Clementinus maintained that the different parts of the body are under the dominion of a particular planet or constellation. King John II. of Aragon having lost the sight of both eyes, by cataract, had one of them couched by a Jewish physician, and recovered it. The Jew being, like almost all physicians of his time (1468), an astrologer, declined to operate on the other eye, as the planets wore a malignant aspect. The king, superior to such foolery, overruled the objection, was operated on, and recovered his sight perfectly. At this time Jewish physicians were in great request at all the courts of Europe. (Prescott.)

Such influence had these absurdities over the minds of men that the astrologer-physician Culpeper, a man of some learning, wrote his practice of medicine founded on astrological principles, and in his preface modestly prophesied that his work "will profit millions until the world becomes one great bonfire." The character given of this man (Sidrophel Vapulans, 1699) was, "Culpeper was an impudent quack-astrologer and a rebel. He libelled the learned King James, and that most pious prince his son, and d——d them both to h—ll, together with the whole college who compiled the London Pharmacopœia."

Rupaldi insisted on the particular days when bloodletting should alone be practised; and a scruple of violating these rules, which other physicians equally insisted on, was declared to have often caused fatal results. In several countries of the East, these absurdities are still relied on. In Turkey, the Astrologer Royal is referred to in questions relative to the Sultan's health, and to every public measure of importance. In China an astrological calendar is annually published by royal authority, in which the fortunate days for taking physic or a wife, and all other important things, are accurately noted. In the Persian calendar, also, the fortunate days for taking physic and marrying, with various other particulars, are given; as also predictions of political and natural events; and it must not be forgotten that we find the same kind of information in one or two of our still remaining astrological almanacks in Great Britain.

The Persians highly respect the astrologers, and speak of the planets in the following beautifully conceived terms:—"Praise be to that great Creator, who formed heaven and earth, and the heavenly bodies; among whose divine works mankind appear but a small spot. The dark Saturn, like a sentinal, in the seventh heaven, is attentive to his interests; the glorious Jupiter, like an able judge, enthroned in the sixth heaven, is watchful of his desires; and the bloody Mars, with his stained sabre, sits in the fifth heaven, the ready executioner of his Maker's wrathful commands; and the resplendent Sun, encircled by a flaming crown, shines in the fourth heaven with light that he has received from the Almighty; the beautiful Venus, like a glad minstrel, sits in her elegant apartment in the third heaven, supported by his power; the feathered Mercury, like a wise secretary, sits in the second heaven, the writer of the Almighty's orders: the clear moon sits enthroned in the first heaven, a sign of the Creator's power." (Fowler's Three Years in Persia.)

In the Egyptian economical calendar, information or

advice is given for every day in the year, along with some astrological observations. Amongst them are many important remarks, such as—"Sitting in the sun is oppressive—Bugs make their appearance—Increase of bugs—Times mend—Worms and grass-hoppers breed—τὸ πλησιαζειν γυναικι is now very wholesome—Increase of heat; fleas diminish—Take care not to eat too much—Avoid τὴν συνουσίαν and eating onions—Drink cold water on an empty stomach—Evita τὸ παρακοιτεῖν—Water drinking at night is injurious—Do not bleed except in cases of the greatest necessity (Oct. 24)—The passages of the nose are stopped—Increase of fleas (Dec. 19)—Don't eat beef (Dec. 22)—Don't eat fowl (Dec. 29)—Conclusion, and 'God knows the truth of all things, and the fate of the humble Yehia' (Editor of the Almanack), and he then offers up a prayer for himself, and his parents, and all Moslems." (Travels of Augustus St. John, 1834.

The Jesuit Du Halde says the Chinese astrologers "distinguish the hours proper for everything, not unlike our Shepherd's Kalendar, wherein are marked by characters the time to let blood, undertake a journey, fell wood, sow, plant, &c. They point out the lucky minute to ask a favour from the emperor, to honour the dead, offer sacrifice, marry, build houses, invite friends, and everything else relative to public and private affairs; and all this is observed so scrupulously by many that they dare do nothing contrary to the direction of the Kalendar, which they consult as their oracle." (p. 133.)

"On the first day of the second month, the Kalendar for the following year must be presented to the emperor, who, having seen and approved of it, the under officers of the Astronomical Tribunal add to each day the superstitions before mentioned. Afterwards, by the emperor's orders, they are distributed among the princes, lords, and great officers of Pe-king, and sent to the viceroy of every province." "The Kalendar is distributed every year with a great deal of ceremony." "In short, the Kalendar is so highly reverenced by the Chinese and their neighbours, and of so great importance to the state, that to declare one's self subject and tributary to the prince, it is sufficient to receive his Kalendar, and to refuse it is the same as setting up a standard of rebellion."

A Chinese saying is, "that all the constellations preside over the empire of China, so as to concern themselves with no other countries."

Astrology is cheap in China, "the country is full of those people who calculate nativities. They are generally blind, and go from house to house playing on a kind of theorbo, offering to tell one's fortune for about a half-penny." (Description of the Empire of China, 1741.)

"The attachment (says Earl Macartney) of the people to such notions is confirmed by every accidental coincidence of the prediction with that event; while the frequency of disappointment is considered as arguing only the ignorance of the practitioner, not the fallibility of the art. New and many oracles are consulted, in hope they may agree; and thus what ought to put an end to the credulity of dupes to such impostures, serves only to increase the business of those who carry them on." (Embassy to China.)

CONCLUSION.

From the preceding history we learn that, in almost all ages down to the present hour, the absurdity has prevailed of believing that the glorious host of the heavens is displayed for the perusal of the trivial events which constitute the history of human life. Much controversy has been expended in constructing a definition of Man. The proposition "man is a credulous animal," seems to be as adequate as any other.

We also learn, that physicians are as liable to be deceived by popular delusions as other men—a useful lesson if it had the effect of guarding their successors from the various forms of deception with which the world at all times teems, and which are sure to meet a willing reception from the mass of mankind.

11, Clare-street.

THE PATHOLOGY OF INFLAMMATION AND FEVER.

By H. Freke, A.B., M.B., M.R.I.A., Dublin.

(Continued from p. 85.)

The first proposition which I have undertaken to attempt to establish is as follows: viz., 1st. That during acute inflammatory action, there is not (as is I believe generally supposed) any augmentation whatever of the normal amount of fibrin contained within the *system generally*; that, on the contrary, the actual amount of fibrin contained within the general system is not necessarily affected in any way by the occurrence of inflammation; but that the *local* accumulation of fibrin—that is, the augmentation (on the occurrence of acute inflammation) of the amount of fibrin normally contained *within the vascular parietes* is the result of the normal extravasation of fibrin from the vascular system into the extravascular interstices having for the time been suspended. That is, the fibrin which normally would have been extravasated from the vascular system into the extravascular interstices (to be there appropriated to the purposes of nutrition) is, during the inflammatory process, retained *within* the vascular system, thereby causing an accumulation within the vascular parietes of that fibrin which, under normal circumstances, would have existed *extravascularly*.

In order to establish this proposition, the first topics to which it will be necessary for me to direct my readers' attention are the following—namely, the *generation* and the *appropriation* of fibrin. In relation to these topics, it will be necessary that the following four facts should be clearly and distinctly ascertained—namely, the manner and place in which fibrin is generated, and the manner and place in which fibrin, when generated, is appropriated to the purposes of nutrition. I shall consequently proceed to the investigation of the following important inquiries—namely, 1st. How and where is fibrin generated? and 2nd. How and where, when generated, is fibrin appropriated to the purposes of nutrition? A full and complete investigation of the first of these inquiries (viz., how is fibrin generated?) would obviously involve a detailed inquiry into the entire process termed "cyto-genesis" or "cell-growth," which for many reasons would be here undesirable, and among others as drawing the attention of my readers too far from the subject under immediate consideration. There are, however, one or two facts in connexion with that process which I feel it to be indispensable to lay clearly and distinctly before the view of my readers, and that inasmuch as the facts to which I refer are not (as I believe) generally known to the profession, while I regard their recognition as absolutely essential to the formation of sound views upon the pathology of inflammation. Should my preliminary observations appear to any of my readers to be either prosy or unimportant, they will have the goodness to bear with me for a while till they be enabled to recognize the importance of their application. It is a fact which, since the invaluable researches of Sehliden and Schwann, is well known to every physiologist that all organized structures have their origin in some way from what are termed "nucleated cells,"—that is, from a species of membranous envelope containing in its interior one or more microscopic granules termed nuclei. To these nuclei have been given the name "cytoblast" or "cell-germ." The real nature of these so-called "cytoblasts" or "cell-germs" appearing to me to be still involved in obscurity, I some time ago proposed to myself for investigation the following inquiries—namely, 1st. The nature of the function of each individual so-called "cytoblast" or "cell-germ," as also the requisites essential to the discharge of that function. 2nd. The nature of the relation which subsists between these so-called "cytoblasts" or "cell-germs" and their *cell*—that is, in other words, the manner in which a so-called "cytoblast" or "cell-germ" *forms or generates a cell*. And 3rdly. The nature of the relation in which these so-called "cytoblasts" or "cell-germs" stand. 1st. With regard to inorganic or mineral matter. 2nd. With regard to each other. And 3rd. With regard

to those other organic structures (distinct from these so-called "cytoblasts" or "cell-germs") which are found in the constitution of organized beings; such, for instance, as woody fibre, muscular fibre, nervous tissue, glandular structure, &c. &c. In relation to these inquiries, I attempted to establish the following (as I believe *altogether original)* propositions—namely, 1st. That the true and appropriate appellation of the ultimate organic molecule, or of these so-called "cytoblasts" or "cell-germs," is "*Organizing Atom.*" 2nd. That the manner in which these so-called "cytoblasts" or "cell-germs" generate a cell is closely analogous to that in which a body radiating caloric may become surrounded by (as it were) an envelope of the matter to which it *imparts* its caloric. In a manner, for example, closely analogous to that in which the *water*, contained in a vessel which has been placed in the centre of a mass of ice, may be converted into *ice*, while in becoming so converted it imparts its caloric to the surrounding ice, converting it into water. As a final result in such case, we have a nucleus of *ice* surrounded by an envelope of *water*. In connexion with this subject, I attempted to point out the function which Nature has designed should be performed by the so-called *incidental* components of organized structures, such, for example, as potassium, sodium, phosphorus, and the like. 3rd. That these so-called "cytoblasts" or "cell-germs" so exist in nature as to constitute an unbroken chain of distinct organisms, gradually ascending in the scale of organization from the humblest "cell-germ" in the vegetable kingdom to the most elevated in the composition of man; and that the several links of this chain are, as it were, united or cemented together by one of the products of the function of each. And 4th. That the specific function of each link in that ascending chain of organisms—that is, "the special function of each individual so-called "cytoblast" or "cell-germ" is to generate or create *a specific description of organized matter* which is essential, and which alone is competent, to call into *normal* operation the specific function of the link or "cell-germ" next above it in the ascending chain of organisms or "cell-germs;" between which specific description of organized matter and that "cell-germ" which it is capable of calling into action (that is which it is capable of arousing or exciting to the normal discharge of its specific function), nature has placed a strong force of affinity or attraction analogous to that in the inanimate world which subsists between potassium and oxygen; and that thus through the agency of this specific product of each of the several links in the ascending chain, all the various links in the great organizing chain are united, or as it were cemented together.

As these four deductions may require a moment's further explanation, I shall as briefly and as rapidly as is consistent with perspicuity make a few observations upon each. I do so inasmuch as till I have clearly conveyed to my readers' mind the meaning of these deductions, and attempted to convince them of their soundness and importance, I shall have no basis or foundation whereon to erect my superstructure—no source from whence to derive any deductions in the pathology of inflammation and fever. First, then, as to wherefore I have proposed the adoption of the terms "organizing atom," and why I consider such appellation of importance. Upon what grounds I am of opinion that such designation of the ultimate organizing molecule is to be preferred to the term "cytoblast" or "cell-germ." It must be obvious to every one that in a science like physiology the nomenclature cannot be regarded as a consideration of inconsiderable moment, inasmuch as thereby may be conveyed, perhaps in a term, the most correct or the most erroneous impressions. How should this nomenclature be regulated? How, or upon what principles, should the nomenclature in *every* science be constructed? To me it appears that the most appropriate and philosophic appellation that can by possibility be applied to *any* entity (be its nature what it may, or to whatsoever science it appertain) must of necessity be that which, without involving in it any hypothesis or theory, makes the nearest approach towards the expression of the *constitution* and the *specific function* of that entity. Let us then inquire if we can learn anything as regards—first, the constitution; and secondly, the specific function *of the ultimate organizing molecule*. First, then, as to the *constitution* of that molecule. It is well known to every one familiar with physical science that several phenomena in the inorganic or mineral world (such as the laws of chemical combination, crystallization, &c.) have led to the very strong presumption that all inanimate matter is composed of ultimate indivisible molecules, which molecules, from their supposed physical indivisibility, have received the very appropriate appellation, *Atoms*. Notwithstanding, however, the strong presumptive evidence in support of such opinion, the infinite physical indivisibility of inanimate matter can scarcely be said to have been actually demonstrated, and the atomic constitution of *mineral* matter must still be regarded as hypothesis or theory. Does it follow from thence that such must be also the case with regard to *living or animate matter?* Does it result as a necessary consequence of our uncertainty as to the absolute *physical* constitution of *inanimate* matter that the infinite *physiological* indivisibility of organized beings must also be matter of doubt or hypothesis? To my mind no such consequence results. I have no hesitation in stating that, to my mind, it appears to admit of the clearest demonstration that the infinite *physiological* divisibility of organized beings is utterly and absolutely impossible, and that consequently the *atomic constitution* of *living* creation is as much matter of demonstration as is any recognized fact in the science of physiology. Let my readers distinctly understand that there is a marked and important distinction between physical or chemical and *physiological* division. It is needless to point out what constitutes physical or chemical division. What do I understand by the terms *physiological* divisibility? What I understand by physiological divisibility is this—namely, such a division of any physiological entity as does not destroy or affect the physiological properties essentially and specifically appertaining to that entity. I shall illustrate. A fasciculus of muscular fibres, for example, may be physically and at the same time physiologically divided into its several component muscular fibres, each of which may retain undestroyed and unaltered the properties which essentially and specifically belong to muscular fibre. Hence in this case such muscular fasciculus may, with the strictest propriety of language, be said to have been *physiologically* as well as physically divided. But if, instead of dividing that fasciculus into its several fibres, such fasciculus be triturated to a fine pulp in a mortar, its division is still physical, but it is no longer physiological, for the result no longer retains the physiological properties (unaffected or unaltered) which essentially and specifically belong to muscular fibre. Or if that fasciculus of muscular fibres be reduced to its elementary components, the division is chemical, but not physiological, for the physiological properties of muscle have been altogether destroyed. To me it appears that in every organism there must of necessity be a point beyond which physical or chemical division cannot possibly be carried without of necessity destroying the physiological condition which is essential to constitute what we understand by an organism. What is an organism? By the term organism I understand *an integral capable of manifesting an independent vitality.** Such integral can (as I conceive) exist, as regards its constitution, in but one of two conditions—namely, it must (as it appears to me) be either *simple* or *compound*—simple, that is comprised in a *single*

* My readers will please to understand that by the term *organism*, wherever employed in these papers, nothing more or less is meant than simply an independent living being: or a being which is capable of living independently when placed in circumstances adapted for so doing. To organized structures of a totally different nature, such as muscular structure, glandular structure, &c. &c., the term organism is here *never* applied. The marked distinction in the nature of these two species of organized structure—namely, organisms and organized structures which are not organisms) will become manifest as we proceed with our inquiries.

individual organism, as may possibly be the case with regard to some of our lichens; or compound, that is composed of a *plurality* of organisms which, in *combination*, constitute a compound or aggregate integral, such, for example, as the loftier plants, animals, and man. Such combination may with propriety be termed a *compound organism*. Upon the nature of the distinction between simple and compound organisms, I shall enter more at large as I proceed. If the organism be simple (that is uncompounded of a plurality of organisms), then its physical or chemical division must (as it appears to me) of necessity destroy that condition which constituted it an organism. For otherwise I cannot understand how there can be any distinction; in the former case (that is in the case of its *physical* division) between an organism and any organized matter whatsoever, such as woody or muscular fibre, &c. &c.; or in the latter case (viz., of *chemical* division), how there can be any distinction between an organism and mineral matter. And if the organism be a compound or aggregate integral, such, for example, as man, then its physical division can (as it appears to me) only be *physiologically* carried (like the division of the muscular fasciculus into its fibres) so far as to reduce that compound organism to its simpler or component organisms. All further division of these component organisms must (as I conceive) of necessity destroy the condition which constitutes an organism. It consequently appears to me that such component organisms may, with the strictest propriety of language, and without involving any hypothesis or theory, be *physiologically* said to be *atomic*. The force of the foregoing observations will become much more clearly intelligible when I have entered into a fuller detail of the nature of simple and of compound organisms, and should there be any of my readers to whom the line of reasoning I have pursued may appear to be either obscure or inconclusive, I have only to request that they will have the goodness to suspend their final judgment until I have laid before them in detail what I conceive to be the true nature of a simple and compound organism. Being thus led to regard the ultimate organizing molecule as *physiologically atomic* as regards its constitution, I next asked myself what must be the specific physiological function of that atom. For in constitution and specific function, as already observed, I recognized what to me appeared to be the elements of the most perfect nomenclature. Reflection soon told me that the specific physiological function of every organism must be *to organize*. Yes, the specific physiological function of *every* organism, from the simplest to the most complex, from the lichen to man, is (as it appears to me) to organize; or in other words, to confer organization upon materials distinct and apart from those which form a portion of its own constitution. Let me be distinctly understood in this statement. What do we understand by the terms *specific function*. By *specific* function I understand that function which is possessed exclusively and alone by a species, and which is common to each and every individual of that species. That to organisms (or organizing agents) *alone* belongs the function *of organizing* (that is of conferring organization upon materials apart from those which form a portion of their own constitution), is a fact that few physiologists will question; for the possession of the power of conferring organization is what constitutes what I understand by an organism, or an organizing agent. A complex organism, such, for example, as man, has doubtless a multiplicity of functions to fulfil, but among those functions, there is no one will question, that of conferring organization upon materials distinct and apart from those which form a portion of man's own constitution. But the simplest or humblest vegetation has but *one solitary* physiological function to perform, and that one is *to organize*—that is, to confer organization upon mineral matter. Hence it is obvious that the sole physiological function which can by possibility be common to that vegetation and to man, is that of organizing or of conferring organization upon something. It consequently becomes apparent that the specific physiological function of every organism (regarded merely as an organism) must be to organize or to impart organization to materials distinct and apart from those which form a portion of its own constitution. I am not ignorant of the advantage it might be attempted to take of this statement, but I make it advisedly, and as the result of mature and deliberate reflection. From the fact then (as it appears to me) of the *physiological* indivisibility of the ultimate organizing molecule, in connexion with the fact of its specific function being (in common with *all* organisms) that of organizing or conferring organization, I ventured to propose the terms *Organizing Atom* as a fit and appropriate appellation for that molecule. I have done so from its appearing to me to be at once philosophic and descriptive, comprising what I regard as the essentials for the most perfect nomenclature, conveying in a word the constitution and the specific function of the entity to which it is applied. I have preferred it to either of the terms "cytoblast" or "cell-germ," and that for this reason, that such terms appear to me to be not only unphilosophical and undescriptive, but further objectionable, as calculated to mislead by conveying a very erroneous impression of the true nature and function of the objects to which they are applied. More I should not feel myself justified at present in adding upon a topic which to some of my readers may perhaps appear to be not only uninteresting and unimportant, but to have but slight relation to the pathology of inflammation and fever. My belief is to the contrary; and thus much I have felt it to be incumbent on me to state, inasmuch as the conviction is on my mind that until we have clear and accurate ideas as to the nature of early physiological operations, it is hopeless to search for an insight into the true nature of pathological phenomena. The terms *organizing atom* will frequently recur in these papers, and I felt it to be indispensable at the outset to lay thus briefly before my readers an outline of the grounds upon which I propose its adoption, as also the special meaning I desire to attach to such terms. There may, perhaps, be some to whom *as yet* the foregoing observations may convey but little that is intelligible; I trust, however, as I proceed, their true import will become apparent, and that when I have fully laid before my readers what I regard as the true nature of an organism, both simple and compound, they will be of opinion that nothing has been here advanced upon the constitution and function of the ultimate organizing molecule which is either inconsistent with what is intelligible or unimportant in relation to the topics under immediate consideration. In my next communication I shall proceed to offer a few observations upon my second deduction.

(To be continued.)

Paris, August, 1851.

PECULIAR FORM OF THROMBUS OCCURRING DURING LABOUR.

By William F. Montgomery, A.M., M.D.,
Professor of Midwifery, &c., to the King and Queen's College of Physicians in Ireland.

(Communicated by the Author.)

There are two situations in which the formation of a thrombus or bloody tumour during natural labour is a matter of common observation,—namely, on the head of the child, and at the vulva of the woman; but I think I have fully satisfied myself that there is a third variety of it to be met with in practice, invested with no little interest, and involving considerations of much practical importance,—where an effusion of blood takes place in the tissue of the uterus, near the os uteri, and more especially in the anterior lip of that organ.

On the first variety, or that which forms on the head of the child, I do not propose at present to make any observations. With regard to the second, it does not appear to have been recognized, or, at least, was not described by any English writer,* until Dr. McBride of this city pub-

* The following passage from Veslingius, in 1647, appears to describe this accident very exactly:—"Alias jam bis observassem ab effuso intra tunicas vaginæ sanguine in partu difficili, pudendi labium ingenti tumore distensum fuisse, quo aperto, sanguineque atro paulatim evacuato, mulieres evasere."

lished an account of two cases of it in 1776. Nor do I recollect to have met with an instance of it in my own practice for several years, until 1849, when I met with two within six weeks, the first on the 23rd August, and the second on the 4th October.

The former was in a lady with her first child; her labour was short and natural, with but little effort or straining, nor was I aware of the occurrence of the tumour until after delivery, when I found it on the edge of the left labium, but ruptured, and its contents partially discharged. The swelling subsided within a few days, and no subsequent inconvenience was experienced from it. The lady, who was not young, recovered very favourably.

The second case occurred in a lady who had three or four premature children, and now for the first time, under my care, went to the full period of gestation. I was sent for at six a.m., and her labour proceeded favourably during the next two hours; and at eight o'clock I thought the child's head would be expelled in a few minutes. I now observed, however, that there existed a great fulness and thickness of the perineum and external parts, especially towards the left labium, which began to swell perceptibly, and, as it swelled, assumed a dark purple or blackish colour. It gradually became enormously enlarged, and the advance of the head was completely prevented, until at length, a little after nine o'clock, the swelling burst on the inside, under the pressure of a pain, and a considerable quantity, not less than twelve ounces, of coagulated and fluid blood escaped. The pains almost immediately became effective, and the head advanced easily. The child, a girl, was born at half-past nine o'clock, and all went on well; no hæmorrhage of any consequence took place. Nothing was done except laying on a pledget of lint, wet with solution of alum, and making firm pressure with a napkin fastened to the binder. The sloughs came away on the fourth and fifth days, without hæmorrhage; the swelling of the labium and perineum gradually disappeared, and a clean open sore, of a healthy aspect, remained, which gradually healed, and was completely well at the end of four weeks. The rupture of the vessel in this case took place in the perineum, and thence the effused blood percolated through the areolar tissue into the labium.

Two things particularly struck me when this occurrence took place:—1st. The immediate effect produced on the uterine contractions, which were at once impaired, both in frequency and power; and 2nd. The complete resistance which the tumour offered to the advance of the head.

It is a very rare occurrence in private practice. Several friends to whom I have spoken say they have never met with it among their patients. McBride witnessed only two cases, and Denman only three, most of which occurred, or were first noticed, after the labour was over. Davis mentions two or three. Dr. Clarke, who has recorded the results of 3878 deliveries in private practice, does not mention any instance of it. In Dr. Collins' record, too, of 16,414 cases of delivery, there is not, I believe, any instance mentioned of this accident. No unpleasant consequences attended the cases which occurred to me. Denman says:— "But I believe it is void of danger, not having seen or heard of any dangerous consequence from it, or ever found anything necessary to be done, but to wrap the tumefied part in a flannel wrung out of warm water and vinegar, and on the discharge of the coagula, which should not be hastened, to dress the little sore with some soft liniment." Davis says, that "the subsequent hæmorrhage was so moderate as to excite no alarm," and the lady's recovery was speedy and uninterrupted. This is so far satisfactory, but all cases of this kind have not been so exempt from trouble or danger; very free and persistent hæmorrhage having been occasionally found to cause the practitioner much anxiety; and in not a few instances the result has been fatal. In a case of thrombus, which is reported in the *Revue Médico-Chirurgicale*, Mars, 1850, a thrombus formed during labour, and the attendant, a "sage femme," mistaking it for a bag of membranes protruded, unfortunately succeeded, under that impression, in rupturing it, by which an opening was made, from which the blood poured "like water from a sponge." The edges of the laceration were pinched up, and caught between a split stick, which completely arrested the hæmorrhage. The woman, luckily, was not delivered for three days afterwards; no hæmorrhage returned, and she did well.

In a case recorded by M. Stendel, the tumour burst during labour, six or seven pounds of blood were quickly poured out, and the patient expired. Mr. Crosse of Norwich, says, that in a case which he saw during a protracted labour, rupture of the left labium took place, to the extent of two or three inches, followed by great loss of blood, and the patient died undelivered."

Within the last year I saw a case in which a thrombus, about as large as a good-sized red plum, formed in the left labium, in the seventh month of pregnancy, and gave the lady *intolerable annoyance*, so that on the 18th of June I made a very small puncture into it, and discharged its contents; but on the 13th July I was again sent for, and found her in a similar state of distress, from pain caused by a feeling of weight and tension, of which she complained most grievously. She described the sensation she experienced as resembling that produced by the pressure of the child's head when distending the perineum. I found the tumour rather larger than before, and again punctured it, after which the lady suffered no further annoyance. It did not fill again, and on the 24th of August she was safely delivered of a full-grown child. There was no appearance to mark the situation where the tumour had been; nor was there any attempt at its reproduction subsequently.

So far, all the cases alluded to have been of effusion into the external labia pudendi, but I think I have learned from sufficient observation that these are not the only situations in which thrombus occurs during, or in consequence of labour, but that quite a similar accident, though differing much in degree, happens not unfrequently in the tissue of the cervix uteri, and especially in the substance of the anterior lip of the os, giving rise to a condition greatly resembling in some of its characters that which is generally spoken of as œdema of the part, from which, however, it is altogether a different affection. The first time that this matter attracted my attention in practice was in the following case:—

Mr. S. requested my attendance on his wife, on 11th March, 1830, at ten p.m., she being then in labour. The night before she had diarrhœa and some discharge of blood from the vagina; she had six children by a former marriage, and her last was now five years old. I found her with labour established, and with some hæmorrhage, but not much. One part of the lower portion of the cervix, towards the right side, felt very prominent, thickened, and spongy, so as most strikingly to resemble a portion of the placenta; and it appeared to me that it was from this part the hæmorrhage was proceeding. The head presented naturally; the labour progressed favourably, and as the descending head came to press more forcibly into the os uteri, and on the spongy tumour, its contents were discharged; the hæmorrhage ceased, and did not again return, and at half-past twelve o'clock a male child was born, healthy and vigorous. The placenta came away in about ten minutes. There was no further hæmorrhage or other unfavourable symptom, and the lady recovered well. Mr. S. was a medical man, and, seeing the hæmorrhage, he became anxious, and made an examination, when he was greatly alarmed at feeling, as he thought, the placenta at the os uteri, and immediately sent for me.

After hearing his report, I examined the patient, and at the first moment thought his account was only too correct; but a little further examination easily satisfied me of the true state of the case, because it was clearly evident that the tumour resembling the placenta was not merely applied to the inner surface of the uterus, but was identified with the substance of the organ, so that it was impossible to insinuate the point of the finger between them, while it could be readily passed behind or partially around. To those who may not have met with this state

of the parts, I would beg leave to say, that the resemblance of this tumour, when in the form in which it occurred in this case, to the placental structure, is sometimes so close as very readily to deceive an incautious examiner. The circumstances under which we meet with this condition in practice are generally as follows:—About the time when the os uteri is more than half dilated, especially if the waters have already been evacuated, we find that the anterior lip gets gradually, but pretty quickly, fuller, thicker, and more prominent, and, instead of yielding readily before the pressure of the head, and slipping away upwards, it continues to descend as the head is forced downwards; and if we try with the point of the finger to push it past the head, and out of the way, we do not succeed; an unexpected delay now takes place, and a labour which we have every reason to hope would go on quickly, and be completed within a short time, is protracted for perhaps two or three hours, or even more, and the patient's pain increased both in character and duration. At length the swollen labium diminishes, suddenly recedes, and disappears, and very often, at the same moment, some blood is discharged, generally of a deep rich colour, and now the retarded head descends more quickly.

I do not wish to be understood to say that the swollen lip in such cases always bursts and discharges its contents, for such is not the fact, but that this is frequently the result I feel quite assured. I had recently (10th October, 1850) an opportunity of *seeing* this condition of the anterior lip of the os uteri during labour. The lady had four children, and her labour was in every respect satisfactory. Shortly after the discharge of the liquor amnii the pains became urgent, and the anterior lip of the os began to swell, and immediately, as in all other instances of thrombus that I have met with, the propulsive power of the pains was at once impaired, although they continued strong, and returned at short intervals; but still the swollen lip resisted the passage of the head, or at least did not yield, and continued to be pushed down with it, until with each pain it protruded under the arch of the pubis, *of a deep purple colour, like that of black currant jelly;* suddenly it disappeared, and one or two ounces of deep, rich coloured blood flowed away; the pains became in a few minutes much more efficient, and the labour was soon happily completed. The lady recovered well. Is this accident an occurrence of little moment beyond the temporary delay and increased suffering which it causes? or is it one that may have dangerous results? are questions of no inconsiderable importance.

Were I to judge from my own experience alone, I should be bound to say, that I had found both forms of thrombus, the external and the internal, free from *fatal*, though liable to produce *serious* consequences; but the experience and observations of others have shown that the bursting of bloody tumours, wherever situated, has been often a source not alone of great danger, but sometimes even of death. I have already alluded to the occasionally pernicious nature of the hæmorrhage accompanying the thrombus of the external labium, and I recently heard the particulars of a case, and examined the uterus after death, in which, I think, death resulted from a thrombus in the substance of the cervix uteri.

The case to which I allude was brought under the notice of the Obstetrical Society by Dr. George Johnston. The woman had an easy and apparently safe labour, with a breech presentation, and for three or four days afterwards went on perfectly well; but on the fifth day, greatly to the surprise of those who saw the patient, and found the uterus well and firmly contracted, a profuse hæmorrhage took place suddenly, and the patient sank within an hour and a half. After death, it was ascertained that there was in the substance of the cervix uteri, close to the os, at the left side, a distinct cavity, capable of containing a small orange, into which opened the mouths of several blood-vessels.

After a careful inspection of the parts, I felt no doubt that this was an instance of the accident I have been describing; that in fact a thrombus had formed, the cavity of which was filled by a coagulum; that the thin stratum of uterine structure, or perhaps only mucous membrane and areolar tissue, interposed between the cavity of the thrombus and that of the uterus, was gradually attenuated, and at length burst, or sloughed away, allowing, of course, the coagulum to escape, and the open bloodvessels suddenly to pour out a torrent of blood, under the overwhelming influence of which life was extinguished within the awfully brief space of an hour and a half. It is to be observed, that in the case of thrombus of the external labium, related at the commencement of these observations, the slough separated on the fourth and fifth days; and here, in the case now before us, the fatal gush of blood took place just at the same interval after labour. It is but right to say of such a case, that it exhibits one of those unforeseen but perilous accidents against which no human care or caution could guard, or human skill be always available to save the patient's life.

In the month of July of last year, I saw a case which I have great reason to believe was of the kind now under consideration.

A lady affected with varicose veins, which extended all up the lower extremity, and could be traced into the vagina, was delivered, after a natural and favourable labour, at midnight; but shortly afterwards a fearful rush of blood took place very unexpectedly, for *the uterus was well and firmly contracted.* So great was the hæmorrhage, that complete prostration was immediately produced, and when I saw her, she was cold and pulseless, nor had she any return of pulsation in the radial artery for six hours and a half from the time of the sudden hæmorrhage, and during a part of that time the action of the heart could neither be felt nor heard. All this time the uterus remained perfectly contracted, but in the situation of the anterior lip its substance felt as if broken up into a soft pulp, the consequence, as I believe, of the formation and rupture of a bloody tumour. To our great joy, she ultimately rallied under the treatment adopted, and completely recovered.

I believe the formation of a thrombus at or near the os uteri, its rupture, and consequently open state of some vessel or vessels in the cavity thus formed, is very often the real cause of those hæmorrhages after the birth of the child and expulsion of the placenta, where the uterus is found to be well and firmly contracted; and it is to be recollected, that just where the thrombus forms is precisely the situation in which the contractile power of the organ is most feeble; and should it happen towards either side, it is then close upon the very part where the bloodvessels send in the largest supply to the uterus. And I would say, that while we should neglect no general or subsidiary means to check the hæmorrhage, or secure the patient from its dangerous effects, our *greatest security*, under such circumstances, will be obtained by plugging the vagina, while, at the same time, we take the necessary precautions against allowing the uterus to relax and become distended with blood.

If the occurrence of this affection has been described or noticed by any former writer, I am not aware of it; but in the writings of two of our most eminent authorities in practical midwifery, I find in each a passage distinctly bearing upon the view I have here put forth, and, as far as they go, tending to confirm its truth. At p. 271 of his Introduction to Midwifery (5th edit.), the admirable Denman says:—"The uncoloured mucous discharge from the vagina, which pretty generally occurs before labour, on its accession is usually tinged with blood, or a small quantity of pure blood is discharged. This sanguineous discharge, which varies in quantity and appearance in different women, is popularly called a *show;* and it happens more particularly at two periods of a labour,—when the os uteri *begins* to dilate, and when it is finally dilated. In the first instance, it is probably occasioned by the separation of a few of those vessels by which the membrane which connects the ovum to the uterus was originally

bound; and in the second case, by the effusion of some blood before *extravasated in the substance of the os uteri; for this part, in some cases, acquires an uncommon thickness from that cause, independent of any œdematous or inflammatory tumefaction.*" And Dr. Burns observes, at p. 460 of his Principles of Midwifery (9th edit.):—"In tedious labour the os uteri, and even the cervix, sometimes becomes swelled, as if blood were effused into the substance." Where such a condition is recognized during labour, we shall show our wisdom by interfering as little as possible with it; by abstaining from attempts to get the gorged lip of the os over or past the head; and when the head does descend, and is expelled, we should be more than usually slow to withdraw the body of the child, more than usually careful to secure complete uterine contraction, and more than usually watchful of the state of our patient after all is over; although we must, at the same time, acknowledge the painful truth, that, with all the care and caution that the most anxious circumspection can prompt to the adoption of, an accident of this kind may take place under circumstances of which we have no intimation, until alarmed by the urgent danger of our patient, or struck aghast by her unexpected and untimely death.

[Dr. Montgomery would feel obliged by the communication of any fact bearing on the subject of this paper, whether confirmatory or otherwise.]

PROCEEDINGS OF SOCIETIES.

EPIDEMIOLOGICAL SOCIETY.—August 4, 1851.

The last meeting of the first session of this society was held this day at the house of the Royal Medical and Chirurgical Society, 53, Berners-street,—Dr. Babington in the chair.

After the usual routine of business, the President announced to the meeting that the report of the Common Lodging Houses Committee had been presented to the Council, and received by them, to be made such use of as shall seem best to the President and members of that committee.

During the meeting, the President stated that, although there would be a cessation of the ordinary meetings of the society till November, yet the various committees would continue in active operation, and invited communications from members and others on the subject of epidemic diseases generally, to be forwarded for the society to the honorary secretaries, 38, Berners-street.

The paper announced to be read at the reassembling of the society on the first Monday in November, is "On Epidemic Diseases in Iceland," by Dr. Robert Gordon Latham.

At the usual period of the meeting, Dr. McWilliam, one of the honorary secretaries, was called upon by the President to read Mr. Grove's paper

ON THE NATURE OF EPIDEMICS.

Mr. Grove commenced his paper by quoting a saying of the Rev. Sidney Smith, that "words are an amazing barrier to the reception of truth," which he applied to miasmata, mephitic vapours, morbid poisons, and their synonyms, remarking that they were words in common use, but that they conveyed no definite meaning to the mind. He then said that the object of his communication was to elucidate that view which held that the poisons inducing epidemic, endemic, and infectious diseases, must be ranked among the things endowed with life. He argued that the faculty of reproduction was a distinctive mark between animation and mechanism, or between living and inanimate matter; that it was during the reproductive period of existence that the most energetic operations of the vital force were manifested; and that it was during the reproduction of the poison germs within the body that the force of diseased action called for our special attention. He called attention to the fact, that whether we examine an epidemic or infectious disease of plants, of animals, or of man, we find that the essence of the affection is something which has the power of reproducing its species.

Taking, then, this faculty of reproduction as indicative of the existence of a germ, the author classed the agents of disease among living things, and regarded reproduction as the primary law.

Mr. Grove then argued that, if this were a correct interpretation of nature, the germs of disease ought to acknowledge obedience to the same subsidiary laws which regulate or influence animate existences. He divided these laws into the objective and subjective; the former referring to faculties, or properties inherent in the germ, the latter referring to the action of external agents and influences upon them. The laws named, ten in number, are not intended as absolutely definite expressions of a comprehensive idea, but merely as the readiest approximations.

Objective Laws.—1. The diffusion or dispersion of germs. 2. Their static existence. 3. Duration of active existence. 4. Period of development. 5. Intermittent reproduction.

Subjective Laws.—1. Seasons of activity. 2. Climatic influence. 3. Relation to latitude. 4. Subjection to physical forces. 5. Influence of locality.

The application of these laws to the agents of disease was demonstrated, and their analogies traced in the vegetable and animal kingdom. He further showed that, upon this mode of explaining the phenomena of infections, little else was required to solve some of the most difficult problems connected with them.

Having shown the impossibility of accounting for epidemics and infection upon the chemical basis—seeing that in no purely chemical process was there any multiplication of the agents, and that, as far as the physical forces were concerned, one always increased at the expense of the other, as heat increases by the chemical change taking place in combustible bodies—the author concluded by drawing attention to the Registrar-General's return of deaths for the year 1847, by which it might be seen that, as 97,924 deaths were due, nearly one-fourth of the total mortality was attributable to causes especially demanding the attention of this society; and if we were allowed to include consumption, considerably more than one-third, the numbers being, of the diseases mentioned, 151,241, and the total mortality for the year 453,723.

Dr. Babington, Dr. Silvester, Dr. Snow, Mr. Charles Cochrane, and Dr. McWilliam, joined in the discussion.

A vote of thanks was accorded to Mr. Grove, in his absence from the meeting, for his interesting paper.

ON THE OBSTETRIC PRACTICE OF THE VIENNA LYING-IN HOSPITAL.

(Read by Dr. Arneth at a Meeting of the Edinburgh Obstetrical Society.)

In laying before this society the following communication, my only object is to excite discussion on any of the more interesting topics in midwifery which I shall have occasion to notice: and I shall, in commencing, apologise for those imperfections in it arising from my comparative ignorance of the English language. I have now been connected for three years with the Lying-in Hospital in Vienna, as assistant to one of the professors of midwifery in that institution, in whose wards more than 10,000 women have been confined during that time. In the other midwifery clinique, in the same hospital, the number of labours during the same period was still greater; and through the kindness of my colleagues, I had an opportunity of observing all the important and interesting cases which occurred in their department.

In a woman affected with *abnormal vertical inclination of the pelvis*, there occurred a *central laceration of the perineum* during labour, and through which the child was born. The fourchette anteriorly, and the anus posteriorly, were uninjured.

In the cases of two women, there occurred *prolapsus* of the womb at the full term of pregnancy—in the one complete, in the other incomplete. In both cases reposition of the mass was effected, and labour soon supervened.

There were forty cases of face presentation, and in these thirty-five children were born alive; but of these last, four died in the first days after birth. Two of the mothers died. In no case was instrumental interference resorted to; and for fifty years such has been the practice in this hospital.

Twice (once after a very easy forceps case, and once after a natural confinement) a small part of the os uteri, covered with exudation, was expelled with the discharges. In the second case alluded to, the woman was examined on the ninth day after confinement, and there was found a sharp edge in the os uteri, indicative of the spot where the portion had separated. Both mothers did well.

A patient, in whom the portio vaginalis had been amputated two years previously, became pregnant. The os uteri did not open spontaneously at all when labour came on. Incisions were made in different directions, and shortly afterwards delivery took place. The mother sank ten hours after the birth. Post-mortem examination showed old adhesions of the uterine peritoneum.

Incision of the cervix uteri was required only in a single other case, one of carcinoma of the cervix. In this case the mother did well.

Two cases of carcinoma uteri occurred. Living children were born, and the mothers made very good recoveries.

Cæsarean section was never performed, except in cases where we believed the narrowness of the brim of the pelvis to be so great, as to render it impossible to drag the perforated child's head through it with safety to the mother. So strictly has this rule been kept, that out of somewhat upwards of 200,000 confinements that have occurred in the Lying-in Hospital of Vienna, between the years 1789 and 1851, the Cæsarean section has only five times been resorted to. All the five mothers died. The children survived the operation, and of some of them there were accounts some years afterwards. Professor Dubois has informed me that he had performed the operation twelve times without having had any successful case; nor is he aware of any practitioner in Paris having been more fortunate. Professor Stoltz of Strasburgh, lately informed me that he had operated four times out of six with good success; nay, in one case he was even fortunate enough to see a mother twice surviving this dreadful operation. Everywhere, on the continent, it is an established rule to perform Cæsarean section in every case of a mother dying pregnant in the seventh month, or later. The essay of Bonchut, which has lately been crowned with the prize of the French Academy, proves that with the last pulsation of her heart the mother dies, and that, consequently, the operation of Cæsarean section may be performed immediately afterwards. In four cases, children were saved by the operation in the Vienna Lying-in Hospital. Two of the mothers died of phthisis, one of eclampsia, one of gangrenous inflammation of the cellular tissue of the neck.

It is a curious fact, that whilst, in all cases of midwifery, we are bound most carefully to save the lives both of mother and child, and when that becomes impossible, to do everything in our power for the benefit of the one life we hope to save—that in cases of mortal wounds inflicted upon the mother, or of her being in articulo mortis *for a considerable time* (where the mother is unconscious, and where there is not the least hope to see her restored), accoucheurs too often delay the operation till unfortunately the child in utero is dead. We are of opinion, that in such cases, and more particularly if we ascertain that the child's pulse is becoming slower and weaker, the Cæsarean operation ought immediately to be performed.

A very frequent cause of the child's death during labour is prolapsus of the funis. We are of opinion, that under certain conditions, the following mode of management has been, generally speaking, much neglected: we mean the artificial replacement of the funis. When the head is presenting, and still moveable on the brim, and the os fully dilated, the best plan is to push the funis back, and lay it down in the hollow of the neck of the child. The registers of the Vienna Lying-in Hospital contain forty-three cases of this reposition of the funis. In these, thirty-eight children were born living; and it is only fair to state, that in three out of the five cases of failure, there was scarcely any pulsation in the cord at the time when it was pushed back; and in one other case where the operation had been performed, the labour proved so slow that the forceps were applied for inertia uteri. No hospital report, as far as I know, affords better results of the treatment of a large number of cases of prolapsus of the funis.

The whole prolapsed loop of the funis is taken in the hand, and pushing the child's head a little back, we lodge it in the hollow formed by the child's neck. It is not necessary to say, that the funis is in this way protected on one side by our hand, and on the other by the hollow of the neck, in which it is allowed to lie. There is no reason to fear the occurrence of any injury from compression of the child's head. This operation does no injury to the mother; and, by exciting the uterus to fresh contractions, it sometimes renders the confinement much shorter.

In the cases which have come under my care, the funis, after being replaced, has prolapsed again in only one instance. It was again replaced with complete success. I know, however, the particulars of one case of frontal presentation, where the funis so tightly embraced the forehead of the child, that reposition was found impossible.

Sometimes, when it is impossible to feel any pulsation in the prolapsed funis, the child may be still alive. Four such cases came under my notice, where the funis had been pulseless for so long as half an hour, and the children were born living. As there is rarely time, in such cases, to make use of auscultation, my opinion is, that in all cases fit for reposition it should be performed, unless the funis be very cold and discoloured, or other decided symptoms of the child's death be present.

In the 6608 cases that were under my care, operative interference was resorted to 95 times—that is, nearly once in every 70 cases; 11 of the 95 mothers died—that is to say, 1 out of every 9.

62 children out of the 95 were born living, and 49 survived the ninth day after their birth—that is to say, the day when they used to be dismissed from the institution; so that we lost sight of them after that time.

Turning was resorted to 44 times, or once in every 150 cases; the forceps were used 45 times, or once in every 146 cases; the child's head was perforated 4 times, or once in every 1652 cases. Premature labour was induced twice.

In the post-mortem examinations of some women who died of spontaneous rupture of the uterus, we are at once struck with the immense increase of the size of the fundus uteri, whilst there does not appear to be a similar state of the cervix. It is highly probable that in such cases the rupture is brought on by the immense force exercised by this hypertrophied part of the fundus, and which the cervix is unable to resist. The direction of the laceration laterally speaks for this view. The occurrence of rupture is much favoured if the texture of the mucous membrane has been softened by a previous inflammation. In one case of rupture, the peritoneum alone was affected. The laceration was situated over the fundus of the uterus, and was several inches in length.

One case occurred, in which a woman complained so much of violent burning pains in the abdomen, and was so affected with dyspnœa, that the use of the forceps was deemed necessary. The operation was easily performed. The peculiar characters of the dyspnœa, the complete arrestment of the action of the diaphragm, and the similarity of this symptom to what had been witnessed in a previous case of rupture of the uterus, led us at once to diagnose this as also a case of rupture. For some days after delivery these symptoms almost disappeared, and the pulse improved in character, only a minor degree of asthma persisted. On the seventh day after delivery she commenced to sink, and died suddenly. The uterus was ruptured at the cervix, but the peritoneum was entire.

There were thirteen cases of eclampsia; four of the mothers died, eleven children were born living. Only one breech presentation occurred; it was in a twin case.

All the other children presented with the head. In six cases we resorted to the forceps; the other cases were terminated without artificial interference. We cannot agree with the opinion of Ramsbotham, that the disease occurs most frequently in hot seasons, as there was only one case in May, two in April, four in February, one in December, two in November, two in October, and one towards the end of September. Most of the children (ten) were males; the mothers were, generally speaking, young females, pregnant for the first time. In the post-mortem examinations no morbid symptoms were discovered in the brain. Our treatment consisted in blood-letting, cold water dressings on the head, and the use of tartar emetic. It is worth notice, that very generally after the coma that follows the convulsions, and lasts occasionally for many days, there is to be observed a state of forgetfulness, being sometimes the only remainder of this dreadful disease. I repeatedly saw women who had not the least desire of denying their being pregnant, who could not recollect at all the particulars of their confinement; nay, even of their having been pregnant. This circumstance is most interesting also in a medico-legal point of view.

In the following case chloroform proved very useful. A recently confined woman, who, as she told us, had never suffered from spasms of any kind, complained, a few days after a natural labour, of fever, and pains in the abdomen. These symptoms, however, subsided in a short time. A few days afterwards she suddenly began to howl like a dog, to contract her face in a most ridiculous manner, and to be exceedingly restless. As often as we put some chloroform under her nose, she regained her consciousness, and when asked, complained of no pains at all; but the aforesaid symptoms reappeared immediately when the chloroform was removed. These symptoms lasted for three hours, when we put her, by means of chloroform, into profound sleep; at once all the symptoms yielded, but reappeared in a few minutes after she awoke. I applied chloroform for a second time, and allowed her to remain under its influence for about one hour and a half. After that time she remained entirely free from the symptoms of threatened mania.

From the few cases where chloroform was used in our midwifery practice, and these were all cases of long-lasting and exhausting operations, it would appear that this medicine has a particularly soothing influence on the vascular system; for in all these cases the heart's pulsations were, after delivery, scarcely quicker than in a healthy person; and I may here observe, that in the Vienna hospital for the last two years, nearly all surgical cases have been anæsthetised when operated upon.

In cases of hæmorrhage after delivery, if there are no clots or portions of the after-birth in the womb, contractions are, if possible, excited first of all by frictions. In the very rare cases where the frictions have no effect, we resort to cold water dressings externally; and if these prove inefficient, we inject cold water into the uterus. This treatment has been so successful, that out of more than 20,000 cases that occurred in the clinique since 1833, there are only two cases on record of women dying of post-partum hæmorrhage; that is to say, one of a woman where assistance was only resorted to when she was already moribund, and the second a female taken with small-pox, where every means proved inefficient.

In the period extending from 15th October, 1847, to the end of October, 1848, only one out of 128 mothers died. The mortality increased in November, and still more in December, when one mother died out of every fifteen delivered.

These unfavourable results were undoubtedly caused by the political events of that period. It is not necessary to state how depressed in mind the most of the women confided to our care must have been at a time when their friends, fathers, and brethren, fought either in the ranks of the rioters or in those of the soldiery. But, moreover, one of the wells that supplied some of the yards of the large hospital with water was destroyed by the troops The consequence was, that cleanliness could less effectually be looked for, which we may boast is maintained at other times in our hospitals. The supplies of straw, coverlets, and so on, were also intercepted.

Towards the end of October, when the stores were almost exhausted, and no fresh provisions arrived, many women were confined, and the consequent disease became more fatal in December.

The first cases of puerperal fever that came under our care showed in their beginning no other symptoms than sores near the fourchette that extended widely into the vagina, and over the perineum. They appeared about the sixth day after confinement, were uneven, of a grayish colour, and covered with a corroding matter; they bled very seldom. Sometimes they healed by granulation, but this went on very slowly, the patients meantime becoming extremely emaciated. Other cases proved fatal, the post-mortem examinations showing inflammation of the mucous membrane of the uterus and of the peritoneum; and more generally still of phlebitis.

In the subsequent course of this epidemic of puerperal fever, peritonitis, at other times peritonitis combined with pleuritis, were the more general symptoms. In the course of three days I had the sad opportunity of seeing two cases of phlebitis, ending in the destruction of the eyeball by metastatic purulent deposits. In the first case, only two hours, in the second, eight hours, elapsed between the first symptoms of disease appearing in the eye, and the lamentable catastrophe. It was highly interesting to observe how entirely puerperal fever ceased in our wards after cholera made its appearance. During the month of May and the first days of June, eleven mothers died of puerperal fever; on the 10th of June we saw the first patient under cholera, and had occasionally cases of it till the 11th of August. During this whole period we had only very few patients complaining of the slighter puerperal symptoms, in no case ending fatally. Almost immediately after the disappearance of cholera, the cases of puerperal fever became somewhat more frequent, and decidedly more dangerous —*Edinb. Monthly Jour.*

EFFECTS OF INTERMENT IN VAULTS AND CATACOMBS.

By Waller Lewis, M.B. Cantab., F.G.S.

I have carefully inspected between fifty and sixty vaults of the principal churches in London, and have examined the external condition and appearance of more than 22,000 coffins. I have also examined the state of the contents of nearly a hundred. The results of these investigations are so different from what could have been anticipated, and from what was generally believed to be the case, that I think it important to lay them before the profession, previous to the practice of interment in vaults becoming a matter of history.

I may add that I have not relied alone on my own researches, but have taken the evidence of all the clergy, churchwardens, sextons, and undertakers of every parish in which I could possibly obtain it. The following are some of the conclusions I have come to from these varied sources of information. It will be seen that they are all in direct contradiction to the allegations contained in the *Times*.

1. I have never succeeded in obtaining any traces of the presence of cyanogen, hydrocyanic acid, sulphuretted, phosphuretted, or carburetted hydrogen gases, even in the smallest quantity. In several instances I analysed the air of the vaults themselves, and in one only,—namely, in that of St. Mary le-Strand, was there any indication of the presence of any of these. This was sulphuretted hydrogen in a very minute proportion, and there was no certainty of this being derived from the decomposing bodies, which are here only thirty-two in number. I examined gases formed by bodies of persons of all ages, from the still-born infant to those who had survived to the age of ninety-two. The coffins had been in the vaults various lengths of time; those that had been there a week were examined, as well

as those that had remained there a century and a half. Death had been caused by accident, by age, by disease. The latter had been of the most varied kinds—typhus, phthisis, small-pox, childbirth, dropsy, and cholera.

Not one of the above circumstances seemed to influence, in the slightest degree, the composition or character of the gases. These were most remarkably similar in every instance. *All the gases I analysed or otherwise examined were composed of nitrogen and carbonic acid gas, mixed with atmospheric air, and holding decaying animal matter in suspension.* There was but one ingredient that was sometimes present, sometimes entirely absent; this was ammoniacal gas, which was sometimes present in very large quantities. When this was added to the other gases, it overcame all other odour; when it was absent, the smell much resembled that of very putrid moist cheese. In every instance I searched most carefully for the presence of the hydrogenous gases mentioned, but never found the slightest trace of any one of them.

Another proof, if any were wanting, of the absence of sulphur in any considerable quantity as a product of decomposition, is, that although the metal of many of the older coffins had been acted upon, the substance thus formed was always a carbonate, never a sulphuret or sulphate of lead.

2. *All coffins do not become bulged* by the expansion of the elastic fluids within. On the contrary, so rarely is this the case, that it is the exception instead of the rule. In many vaults there was no instance of a coffin that had bulged, or, as the undertakers say, "blown." In 22,000 I could not find 20 that were or had been in this condition. This is to be accounted for by the fact that lead is so porous a metal that it allows the exosmose or transudation of the gases with great facility, more especially when there is pressure within. It is well known that even the iron gas pipes so thickly underlying our pavements cannot be made retentive of the gas.

3. The gases, therefore, are but very rarely pent up; the instances of "blown" coffins not averaging one in a thousand.

4. *The coffin does not suddenly burst, and the escaping gases do not destroy all within reach.* From the most searching inquiries from coffin-makers, undertakers, and all persons most likely to be well informed on the subject, I have never obtained any sufficient evidence of the sudden rupture of a coffin. It is universally the custom of sextons, when they perceive any leaden coffin to be blown, to send to the undertaker for the purpose of having a hole drilled in the upper part of the lead, so as thus to allow the escape of the foul air. During the operation, the parties employed endeavour to avoid inhaling the gas, and sometimes hold a piece of burning wood or paper at the orifice, so as to destroy in some measure the offensive odour I have described. In my opinion, the fact that coffins so rarely become bulged, is to be ascribed to the great porosity of the metal employed. When slightly bulged, the lead, from being thinner than before, becomes more pervious to the contained air.

The action of the putrefactive gases on the human frame, although not so immediately fatal as the *Times* would have us believe, certainly produces many disagreeable symptoms. In my own person, the most prominent among these were nausea, with vomiting, after continued exposure, succeeded by diarrhœa. These are followed on the succeeding day by a throbbing pain in the upper part of the head, great prostration, and entire loss of appetite, accompanied with an unpleasant earthy taste in the mouth. These symptoms, after being experienced for a long time, were followed by a series of boils, accompanied with much phlegmonous erysipelas, and requiring surgical assistance.

On one occasion, however, I was nearly meeting with an exception that would have corroborated, to a certain extent, the assertion that sudden death may occur from such exposure. I was examining the large vault under the church of St. Andrew's, Holborn, which contains about five thousand coffins, partly of wood, partly of lead. They are placed in eight arched culs de sac running off on either side of the central passage. The air in these compartments is in a state of almost complete stagnation, as there is no ventilation in them. The coffins are piled one above another from ten to thirteen high, and reach to within a short distance of the roof. There is scarcely sufficient room to allow a man to crawl on all fours between the upper coffins and the bricks of the arches. Wishing to see how far these compartments filled with coffins extended, I sent the sexton in with a candle. In a very short time, observing the flame begin to lower, and give very little light, I called to the man to come out immediately. He instantly obeyed, and after much exertion and the extinction of the candle, he presented himself in a pitiable condition, his eyes half starting from their orbits, breathing deeply, and evidently much oppressed. Exposure to a current of fresh air shortly revived him. The air being mixed with a large quantity of carbonic acid gas was the cause of this nearly fatal accident—not the presence of cyanogen or any hydrogenous compound.

5. The complete decomposition of a corpse, and its resolution into its ultimate elements, is by no means accomplished in a period of ten years; nor is that description accurate which represents, that at the end of that period nothing "but a few brittle bones are left in the else vacant shroud." On the contrary, so extremely slow is the process under the circumstances, that I have but rarely seen the remains in a leaden coffin, of any age in the condition described. In a *wooden* coffin the remains are found exactly in this state in a period of from two to five years. This period depends upon the quality of the wood, and the free access of air to the coffin. But in leaden coffins, fifty, sixty, eighty, and even a hundred years, are required to accomplish this. I have opened a coffin, in which the corpse had been placed for nearly a century, and the ammoniacal gas formed dense white fumes, when brought into contact with hydrochloric acid gas, and was so powerful that the head could not remain near it for more than a few seconds at a time.

6. *The putrefaction, therefore, is very much retarded by the corpse being placed in a leaden coffin.*

7. If by this assertion it is only meant that the gases should be passed through flame, to destroy the organic particles mixed so largely with them, this can be understood. This difficulty would, however, still remain: except in the few exceptions I have mentioned of blown coffins, the gases are so slowly generated, that no force would be exerted from within sufficiently powerful to expel them. But if it is assumed that these gases can be inflamed like coal gas, I must deny the possibility of this. I tested the gaseous contents of nearly a hundred coffins, some of which contained a considerable quantity of gas. In no one instance would the gas inflame; on the contrary, *in every instance*, it extinguished the flame. In addition to my own experiments, I made the most minute inquiries of churchwardens, clerks, undertakers, and sextons, but I have never met with any person who has actually *seen* coffin-gas inflame. Several have told me that they have *heard* that it does, but they did not know the fact from their own experience. Some of the officials of St. Anne's, Soho, pointed out a coffin to me, which, having some years ago become blown, had been "tapped." They asserted that a long blue flame had been obtained by firing the jet of gas which issued from the aperture. The smell was described as that of sulphuretted hydrogen; but not one of these persons was present at the time. If, therefore, this or any other hydrogenous compound is ever formed as a result of such decomposition, it is an extremely rare exception.

The following are the conclusions I have arrived at from these investigations:—

1. Interment in vaults and catacombs should no longer be permitted. No good object is gained by this practice. The corpses so treated are by this means converted into so many active volcanos, constantly emitting poisonous effluvia into the atmosphere, for an indefinite period.

2. That after a certain interval, during which friends or relatives should have the power of removing any coffin from the vaults to the public cemeteries, all these receptacles should be hermetically closed, and future access thereto forbidden.

3. The use of leaden coffins should be entirely discontinued; they only add to the already exorbitant charges of undertakers. Until a very late period they were constantly stolen from the vaults, emptied of their contents, and sold as old lead.

4. If the object of interment is to allow the human body, after it has served its purpose here, to return as speedily as possible to its elements, and to become perfectly inert, it should be placed in a light wooden coffin, from five to eight feet deep, in a suitable pervious soil.—*Lancet.*

ACCOUNT OF A MAN WHO LIVED UPON LARGE QUANTITIES OF RAW FLESH.

THE following history was published upwards of fifty years ago in the *Gazette of the United States and Philadelphia Daily Advertiser*:—

Somerset-place, October 18, 1798.

MY DEAR SIR,—Having in August and September last been engaged in a tour of public duty, for the purpose of selecting from among the prisoners of war such men as, from their infirmities, were fit objects for being released without equivalent, I heard upon my arrival in Liverpool an account of one of those prisoners being endowed with an appetite and digestion so far beyond anything that had ever occurred to me, either in my observation, reading, or by report, that I was desirous of ascertaining the particulars of it by ocular proof or undeniable testimony. Dr. Cochrane, Fellow of the College of Physicians of Edinburgh, and our medical agent at Liverpool, is fortunately a gentleman upon whose fidelity and accuracy I could perfectly depend, and I requested him to institute an inquiry upon this subject during my stay at that place. I enclose you an attested copy of the result of this; and as it may probably appear to you, as it does to me, a document containing facts extremely interesting, both in a natural and medical view, I will beg you to procure its insertion in some respectable periodical work.

Some farther points of inquiry respecting this extraordinary person having occurred to me since my arrival in town, I sent them in the form of queries to Dr. Cochrane, who has obligingly returned satisfactory answers. These I send along with the above mentioned attested statements, to which I beg you to subjoin such reflections as may occur to you on this subject.—I am, dear sir, your most obedient humble servant,

J. JOHNSTON.

Gilbert Blane, M.D., F.R.S.,
One of the Commissioners of Sick
and Wounded Seamen.

Charles Demery, a native of Benche, on the frontiers of Poland, aged 21, was brought to the prison of Liverpool, in February, 1799, having been a soldier in the French service on board the *Hoche*, captured by the squadron under the command of Sir John B. Warren off Ireland.

He is one of nine brothers, who, with their father, have been remarkable for the voraciousness of their appetites. They were all placed early in the army, and the peculiar craving for food with this young man began at thirteen years of age. He was allowed two rations in the army, and by his earnings or the indulgence of his comrades, procured an additional supply.

When in the camp, if bread or meat was scarce, he made up the deficiency by eating four or five pounds of grass daily, and in one year devoured 174 cats (not their skins) dead or alive, and says he had several severe conflicts in the act of destroying them by feeling the effects of their torments on his face and hands: sometimes he killed them before eating, but when very hungry he did not wait to perform this humane office.

Dogs and rats equally suffered from his merciless jaws; and if much pinched by famine, the entrails of animals indiscriminately become his prey. The above facts are attested by Picard, a respectable man, who was his comrade in the same regiment on board the *Hoche*, and is now present, and who assures me, he has often seen him feed on those animals.

When the ship on board of which he was had surrendered after an obstinate action, finding himself as usual hungry, and nothing else in his way but a man's leg, which was shot off, lying before him, he attacked it greedily, and was feeding heartily, when a sailor snatched it from him, and threw it overboard.

Since he came to this prison, he has eat one dead cat and about twenty rats. But what he delights most in is raw meat, beef or mutton, of which, though plentifully supplied by eating the rations of ten men daily, he complains he has not the same quantity, nor indulged in eating so much as he used to do when in France.

He often devours a bullock's liver (raw), three pounds of candles, and a few pounds of raw beef in one day, without tasting bread or vegetables, washing it down with water, if his allowance of beer is expended.

His subsistence at present, independent of his own rations, arises from the generosity of the prisoners, who give him a share of their allowance. Nor is his stomach confined to meat, for when in the hospital, where some of the patients refused to take their medicines, Demery had no objection to perform this for them, and his stomach never rejected any thing, as he never vomits, whatever be the contents, or however large.

Wishing fairly to try how much he actually could eat in one day, there was set before him five pounds of raw beef, twelve tallow candles of a pound weight, and one bottle of porter: these he finished by half-past ten o'clock. At one there was again put before him five pounds of beef, one pound of candles, with three bottles of porter, at which time he was locked up in the room, and sentries placed at the windows to prevent his throwing away any of his provisions. At two, when I again saw him with two friends, he had nearly finished the whole of the candles, and great part of the beef, but had neither evacuation by vomiting, stool, or urine; his skin was cool, and pulse regular, and in good spirits. At a quarter past six, when he was to be returned to his prison, he had devoured the whole, and declared he could have eat more, but from the prisoners without telling him we wished to make some experiments on him he began to be alarmed. It is also to be observed, that the day was hot, and not having his usual exercise in the yard, it may be presumed he would otherwise have had a better appetite. On recapitulating the whole consumption of this day, it stands thus:—Raw cow's udder, four pounds; raw beef, ten pounds; candles, two pounds. Total, sixteen pounds, besides five bottles of porter.

He gets to bed about eight o'clock at night, immediately after which he begins to sweat, and that so profusely as to be obliged to throw off his shirt. He feels extremely hot, and in an hour or two after he goes to sleep, which lasts until one in the morning, after which he always feels himself hungry, even though he had laid down with a full stomach. He then eats bread or beef, or whatever provision he may have reserved through the day; and if he has none, he beguiles the time in smoking tobacco. About two o'clock he goes to sleep again, and awakes at five or six o'clock in the morning in a violent perspiration, with great heat. This quits him on getting up; and when he has laid in a fresh cargo of raw meat (to use his own expression) he feels his body in a good state. He sweats while he is eating; and it is probable owing to this constant propensity to exhalation from the surface of the body, that his skin is commonly found to be cool.

I have often tried what is his heat by the thermometer, and found it to be of the standard temperature of the human body. His pulse is now 84, full and regular.

Though his muscles are pretty firm, I do not think they are so full or plump as those of most other men. He has, however, by his own declaration, carried a load of 300 weight of flour in France, and marched fourteen leagues in a day.—*Phil. Medical Examiner.*

ON THE DANGER OF INCAUTIOUSLY MOVING PATIENTS IN DELIRIUM.—Dr. Todd, in a lecture alluding to this subject, says:—I have met with more than one instance of bad consequences following upon moving a patient in delirium, or just recovered from it, prematurely. About two years ago a man was admitted here for epileptic delirium. Finding that his delirium was very noisy, and disturbed the other patients, I had him moved into a separate ward, when he recovered from his delirium. He was moved up stairs, and shortly afterwards he became delirious again, and died comatose.

I am satisfied, from this and other cases, that there is nothing respecting which we need to be more cautious than as to moving patients either in or just recovered from delirium, even to move them from one room to another on the same floor is dangerous, still more moving to any distance, or to another floor.—*Dr. R. B. Todd in Med. Gaz.*

BITE BY THE COMMON ADDER.

Samuel S——, aged 31, a vermin hunter, was brought to the General Hospital, Birmingham, on Sunday, June 16th, 1850, at twelve o'clock at noon, having been bitten on the cheek by an adder. It seemed that on the Thursday preceding, whilst engaged at a farm-house on Coleshill Heath, destroying rats, his dog found the reptile on a bank. He picked it up, placed it in a small bag he had with him, and carried it home. He handled it freely on several occasions, and it never attempted to bite him. On Sunday morning, at about ten a.m., having taken the creature out of a box in which he had kept it, he proceeded to carry it in his hand to a neighbour. On the road he was asked to show it, and raising his hand in order the better to display it, the reptile darted suddenly and fastened on his left cheek, about half an inch above the angle of the mouth, thence dropping on the ground. He immediately picked it up again, replaced it in his handkerchief, and on arriving at his neighbour's the adder was killed. He described the bite as being instantly followed by acute pain, and by a burning sensation of heat and tumefaction. He experienced also nausea and faintness in his walk to the hospital.

Upon his admission, the entire face presented a swollen appearance, and the parts immediately adjacent to the bite were discoloured, of a livid hue. The pulse was imperceptible, the respiration difficult, the surface cold and clammy. He complained of intense pain about the umbilicus, greatly augmented on pressure, and there was constant vomiting of bilious matter; he appeared wandering as if drunk, and answered questions in a mumbling incoherent manner. The bowels acted frequently and involuntarily, and both blood and mucus were mingled with the motions. He also complained of pain in the throat, and there was some difficulty in deglutition. On examination, a copious secretion of viscid mucus was seen to be adherent to the pharynx. With the approval of Dr. Evans, who happened to be present in the hospital at the time of his admission, a glass of brandy was immediately given him; the bitten parts were then excised by Mr. Blake, who was acting as house-surgeon in my absence, and freely cauterized by a strong solution of ammonia. Dry cupping was afterwards resorted to, and the parts were well smeared with olive-oil. The pain and swelling of the parts still continuing, he was ordered the following mixture:—Sesquicarbonate of ammonia one drachm and a half, decoction of cinchona eight ounces. One ounce to be taken every half hour. Three glasses of brandy directly; a tablespoonful to be given every ten minutes. A mustard cataplasm was applied to the abdomen, and kept there for half an hour, followed by fomentations of chamomile and poppies. Half-past one p.m. The pulse is still imperceptible, and the pain unrelieved. He appears to be sinking, and sickness and diarrhœa continue, together with great thirst. Three p.m. The pulse may now be felt, and the pain about the umbilicus is considerably mitigated. Ten leeches to be applied immediately to the part painful. Eight p.m. Pulse 84, soft and compressible; the sickness has ceased; the pain after the application of the leeches is much relieved; two glasses of brandy this night; an ounce of the ammonia mixture every second hour. June 17th, ten a.m. Progressing favourably. Diffuse cellular inflammation of an erysipelatous character has rapidly extended itself from the wound to the neck and sternum, and to the opposite side of the face; the pulse is hard, 98; the skin hot; the tongue coated with a white fur. To take five grains of calomel, and ten grains of Corbyn's extract of colocynth immediately, and one ounce and a half of the hospital aperient mixture, until the bowels are freely evacuated. Twenty leeches to be applied to the face and upper part of the sternum. The brandy to be omitted. Evening. Copious, dark, and watery motions have taken place; the pulse is 104, full, and incompressible. A spirit lotion to be kept applied to the face. The mixture of ammonia and cinchona to be continued.

18th. Much improved; the erysipelas is not spreading; the pulse 98, compressible; the tongue covered with a white fur, but moist; the skin warm. The bowels have again acted freely. 19th. Erysipelas declining; he can partially unclose his eyes; pulse 90, soft and compressible. The parts adjacent to the bite are assuming the departing and varying hues of an ecchymosis. 20th. Goes on well.

21st. He complains of pain and soreness in the chest; all febrile symptoms have disappeared. Half a pint of ale daily, with meat. He left the hospital on the 28th. A slight yellow discolouration remained upon the cheek; his general health was quite restored.—*Lancet.*

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, AUGUST 27, 1851.

MEDICAL ADVERTISING.

The success of out-and-out advertising proclaims a fact which should not be overlooked by the members of our profession; it tells of the materials of which a large section of society is composed, and suggests inquiries as to the morality of dealing with that section in the way it wishes. In other words, it suggests the old medical maxim, *si populus vult decipi decipiatur*; in fact, raises the question whether fools are to be treated as wise men, the ignorant as the educated, and the fantastical as the sober. That question we are not about to answer, we are only about to remind those who reply to it in the affirmative that if they "take to the advertising line" they had better calculate resources before hand, and learn betimes the art of ingeniously applying these resources in practice. For the information of such candidates we publish the following epistle, addressed in mistake to a respectable medical practitioner by a notorious pill merchant, who does not fortunately even pretend to belong to the medical profession. It demonstrates in a way not to be misunderstood the *modus operandi* of such traders, and proclaims the universality of a taste for their wares:—

London, August 18, 1851.

Sir,—I believe that you sell my medicines, therefore I beg to inquire whether you would like to have any of my handbills printed for you with your name inserted; if so, be pleased to send me your card, that the address may be properly copied, and if you will state what you believe to be the population of the town, I shall be able to form some idea of the number you will require. I will allow you 1*s.* 6*d.* per thousand for their being distributed from house to house, and will send you the amount in postage stamps. It might perhaps cost you a little more than I allow to have the work well done, and if this be the case I am sure you will cheerfully pay any little difference out of your own pocket, as the advantage to you will be more than commensurate with the trifling outlay. I am getting my bills distributed in this way throughout every town in the kingdom, and am informed by a great number of vendors that their sales of my medicines have been greatly increased by such means. If you would like to have one large, or two or three small show-cards, please to say so. I would also be happy to let you have some bills, four times a year, and they could be sent to any house here for enclosure; hence no expense will accrue to you. I have no desire to deprive the wholesale houses of any part of their connexion, and therefore do not wish you to get your supplies of my medicines from here, as you can do quite as well with them as with me, unless £20 worth be wanted at a time, and paid for in cash. I enclose a stamped envelope to cover reply, and remain, sir, yours faithfully, —— ——.

We do not publish this with any view to the correction of its author; on the contrary, while giving currency to it, we feel inclined to hear a plea of justification on his part. He finds men and women, or in political slang, "the people," "society, the public," in want of "a cure," and he supplies it. The worst he can be accused of is a fib, when he asserts that his pills are a remedy for all diseases. He repudiates no solemn obligation, breaks no oaths, glories not in any outrage of common decency; in fact, propitiates not congenial souls by an open avowal of baseness and depravity. Can we say so much for the professional outcast who pursues a similar course? If this man had not come from the mere dregs of society; if he had received such "liberal education" as school and college afford; if he had taken a medical degree and surgical diploma, solemnly swearing, "So help him God," that he would "support the reputation, honour, and dignity" of the pro-

fession he embraced, we might then hold him up to contempt and execration ; but as he is we feel inclined to value him by contrast ; for undoubtedly there are some regularly admitted doctors and surgeons circumstanced as we describe. Perhaps, however, after all, we are too fastidious, and form a false estimate of qualification for medical practice, especially in large communities. No one knows the meaning attached by some to the words honour, honesty, or integrity. Honour for instance there is among thieves, and why not some similar feeling between certain doctors and their patients. Men there are undoubtedly who think nothing the worse of a person for his ability to lessen their disbursements, notwithstanding some slight flaws in his reputation ; such may require the cheap-and-nasty in medical ministration, and may care little whether he who provides it is a knave or not : nay, we even venture to express a suspicion that there are men, and in this our pure metropolis, not a few, who have a kind of instinctive leaning to such characters.

LAW AND PHYSIC.

The following recals to memory many examples of the same display of contempt for medical evidence by judicial functionaries in England in cases of insanity, while a very different feeling prevails in Ireland. Here both judge, counsel, and jury accept the information afforded by members of our profession with respect, and when to be relied on, give it due consideration. To what cause is this to be attributed ? Perhaps just to this. In Ireland physicians and surgeons, as well as lawyers, are better educated than they are in England. We do not allude to professional education, or even to that smattering of knowledge which a man picks up in college, but to a certain general education derived from intercourse with educated people :

During the recent hearing of a lunacy case, the Lord Chancellor is reported to have said—"His experience taught him there were very few cases of insanity in which any good came from the examination of medical men. Their evidence sometimes adorned a case, and gave rise to very agreeable and interesting scientific discussions ; but after all, it had little or no weight with a jury." Whatever may be the respect we entertain for this high authority, we emphatically dissent from these views, believing them to be founded in error, and totally unjust to practitioners in medicine, who are not only the most important but often the only competent witnesses, in inquiries respecting insanity. That medical evidence does not always produce the impression it ought upon the individuals addressed, we readily understand. The judicial tribunal just mentioned, from its miscellaneous composition, must be occasionally unable to form correct conclusions respecting the very intricate points at issue; more especially as even great legal authorities themselves are sometimes far from being unanimous in opinion. Suppose an eminent medical professor were to assert, "ex cathedra," that "the bar of England knew nothing of law, and that very little benefit ever accrued from their speeches. They might adorn a case, make an eloquent oration, or quote precedents, but all their arguments would never influence any twelve men sitting in a box." Westminster Hall would be in an uproar against any member of the medical fraternity who presumed to utter such sentiments ; and we acknowledge the lawyers might, in that instance, justly express their indignation. Each profession should respect the other, in its peculiar sphere, as all, the public included, will then gain by liberal and kindly bearing. As an illustration of the feelings which ought to prevail, allusion might be made to the late Lord Chief Justice, the son of a physician, and an able as well as dignified jurisconsult, when presiding at the trial of Oxford for treason. On that occasion the present Lord Chancellor, then a learned serjeant, having endeavoured to brow-beat a medical gentleman whilst giving evidence, was properly checked by the presiding judge, in order that the witness need not fear any forensic fervour of counsel. We therefore say to our brethren, when called upon to appear in a court of justice,—state facts and opinions clearly, firmly, and fearlessly.—*Lancet.*

THE DUBLIN HOSPITAL GRANTS.

We have much satisfaction in announcing that there is a fair prospect of a favourable consideration of this matter, and that (as far as relates to the educational hospitals at least) the question will be settled with due regard to the interests of science. For this, we are enabled to state with confidence, Dublin is indebted to Lord Clarendon, who, notwithstanding all that has been said to the contrary, we are satisfied, from beginning to end, exerted himself to prevent the alienation of this fund from its original object. Whatever we may from time to time find it necessary to say respecting passing events affecting medical interests, it is only fair play to confess that we believe Lord Clarendon has always proved that he entertains views most favourable to medical institutions, and that he has never failed to carry them into effect when opportunity offered.

NEW KIND OF ARTIFICIAL EYES.

On Saturday, August 2nd, an operation of a rather unusual kind took place in the theatre of King's College Hospital. It consisted in fitting and placing an artificial eye upon a young man of 18, a patient of Mr. Partridge, who had lost one of the organs of vision some time previously. It was certainly very advantageous to the pupils there assembled, that Mr. Partridge should have requested M. Boissonneau to place the artificial eye himself upon the patient in the theatre, and to give a few explanations touching his new method ; as not only pupils, but many surgeons, are hardly conversant with the manner of using such substitutes, and with the remarkable improvements which have lately been introduced into this branch of surgical mechanics. M. Boissonneau showed the artificial eye, which imitated to perfection the sound organ, and having placed it between the patient's lids, it evidently gained a mobility and a consentaneous action with the sound eye, which excited much admiration. The patient was now made to take off and replace it himself; this he accomplished with great facility, owing to the peculiar form and precise adaptation to the globe which had been given to the artificial organ. It seemed that many hardly-to-be-hoped-for requisites had in this instance been obtained : perfect similarity as to size and colour, movements admirably deceptive, facility of taking off and putting on, and complete absence of pain. Mr. Partridge requested M. Boissonneau to enter into some details as to the nature of the improvements which he produced, and the peculiarities of his artificial eyes. M. Boissonneau, in complying with Mr. Partridge's wish, stated that it had formerly been the custom to make such eyes of a uniformly oval shape, very much like the longitudinal half of a bird's egg, and that these would only suit perfectly empty orbits, and had no mobility whatsoever; they therefore had the great defect of a fixed stare, and almost always necessitated the removal of part of the globe by operation. Trials had subsequently been made, in order to adapt the above-mentioned form to pretty large remains of the eyeball, but the margins constantly fretted the parts, caused abundant purulent secretion, and proved very inconvenient. M. Boissonneau was then struck with the idea that it was incumbent upon the enamel modeller to shape and adapt the artificial eye to any form which the globe of the lost organ might have retained, thus avoiding an operation, and gaining for the artificial organ all the mobility which the subjacent globe, aided by the play of the lids, must inevitably give it. After more than ten years trials in France, Holland, and all Germany, he had succeeded in regulating the forms, classifying them, and introducing order and scientific sequence in a hitherto neglected branch of art. We thus perceive that the afflicted have been great gainers by M. Boissonneau's labours, for they escape pain, the similarity is perfect, and the mobility surprising. They can adapt and take off their artificial eyes with ease, and these are even so accurately adapted that they cannot be wrongly put on. We understand also that M. Boissonneau uses a kind of enamel, with metallic bases, which is extremely enduring. As it is unfortunately but too often the case that the surgeon is compelled to declare himself incompetent as to restoring an eye which has either by accident or disease been disorganized, it is consoling that he has at hand such admirable substitutes, which will at least save the patient from carrying with him a deformity which is ever of a melancholy character.—*Lancet.*

MEDICAL DIRECTORY FOR IRELAND.

A CIRCULAR has now been issued to every known Member of the Profession practising in Ireland, containing interrogatories as to Name, Address, Qualifications, &c., for insertion in the Directory, which will be published in January, 1852. Any gentleman who may not have received one, is requested to intimate the same, without delay, to the Editors, 4, Adam-street, Adelphi, London.

DR. JACOB'S PUBLICATIONS ON THE EYE.

Just published, price 1*s.* 6*d.*, free by post, 8vo, pp. 36.

ON THE OPERATION FOR CATARACT WITH THE FINE NEEDLE THROUGH THE CORNEA.

Lately published, small 8vo, price 5*s.*,

THE INFLAMMATIONS OF THE EYE:

A Treatise on all the Species and Varieties of Iritis.

Some time published, 8vo, with four plates, price 5*s.*,

TWO ESSAYS ON THE ANATOMY OF THE EYE, WITH FIVE OTHERS IN COMPARATIVE ANATOMY.

Also, 8vo, price 1*s.*,

ON THE PARALYTIC, NEURALGIC, AND OTHER NERVOUS DISEASES OF THE EYE.

At the Office of the MEDICAL PRESS, 15, Molesworth-street; or Mr. Fannin's, Grafton-street, where Dr. JACOB'S CATARACT NEEDLES may also be had, price 2*s.* 6*d.*

DISPENSING OF MEDICINE.

G. OLDHAM AND CO.,

PHARMACEUTICAL CHEMISTS, AND APOTHECARIES,

From BEWLEY and EVANS',

No. 107, GRAFTON-STREET, DUBLIN,

(Corner of Suffolk-street),

BEG to return their grateful acknowledgments to the Medical Profession for the support they have hitherto received, and which they will regard as a fresh motive for exertion. Abstaining altogether from visiting as Apothecaries, except for the application of Leeches, Cupping, and such operations as are performed under medical advice, they will continue to devote themselves exclusively to the duties devolving on the pure Pharmacien.

Having had much experience in Practical Pharmacy, and being resolved to spare neither trouble nor expense in order to have every article of superior quality, they hope by attention, "carefulness," punctuality, and moderation of charges, to commend themselves to the approbation of those who may entrust them with their commands.

☞ *G. O. and Co. invite attention to their present stock of Surgical Instruments, all of which are manufactured on the most modern and improved principles.*

THE ROYAL MEDICAL HALL,

64, DAME-STREET, DUBLIN.

☞ *Change of Proprietorship.*

BEWLEY, OWEN, AND CO., APOTHECARIES,

(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS,

will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT

embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick-room and nursery.

*** GENUINE COD-LIVER OIL,

of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the city of Dublin. London: John Churchill, 46, Princes-street, Soho.

ORIGINAL COMMUNICATIONS.

EXTENSIVE WOUND OF THE ELBOW-JOINT, WITH SEPARATION OF THE EXTERNAL CONDYLE AND ARTICULATING HEAD FOR THE RADIUS, FROM THE LOWER EXTREMITY OF THE HUMERUS—RECOVERY, WITH PARTIAL ANCHYLOSIS.

By Richard G. H. Butcher, F.R.C.S.I.,
Examiner on Anatomy and Physiology in the Royal College of Surgeons in Ireland;
Surgeon to Mercer's Hospital,
&c. &c. &c.

Thomas McGill, aged 18, by trade a coachmaker, admitted under my care into Mercer's Hospital, June 10, 1851. *History:* The patient and his fellow apprentice had a quarrel, when the latter took up a large heavy knife and made a blow at him, inflicting a very severe wound on the right arm. He was brought at once to hospital, when I saw him immediately after the accident. He was labouring under very severe shock, manifested by coldness of the surface, rigor, and blanched countenance. He had lost a great deal of blood, and was then bleeding profusely. The hand of an assistant, placed steadily over the axillary artery, checked the hæmorrhage, and I proceeded to examine the wound. It commenced about three inches above the joint on its outer and posterior aspect, and with such violence did the knife take effect that the external condyle of the humerus, together with the capitulum on which the head of the radius moves, were split off, everted, and protruding through the wound. From this it will appear how extensively the joint was laid open. The edges of the wound gaped so far apart that the articulating surface of the radius was completely exposed, and its anterior edge marked by the knife, clearly showing that its downward direction was here checked, its force being nearly expended; and then meeting with less resistance, it passed forwards, dividing the supinator and extensor muscles forming the outer prominence of the forearm. On everting the edges of the wound, I tied two large arteries above the joint, which were giving blood very freely, and secured the radial recurrent below: the hæmorrhage then ceased. The piece of the humerus, split off and thrust forward through the wound, was still attached by some fibrous bands behind and externally, so I restored it to its natural position, and then brought the edges of the wound together with adhesive straps, and placed the limb in the semiflexed position on pillows, the hand being raised so as to favour the returning venous current. Heat was then applied to the feet, and a warm carminative draught with opium administered.

Nine p.m. Reaction fully established; skin hot, and pulse bounding; does not complain of pain in the joint. Ordered a full cathartic enema immediately, and in two hours an opiate draught with laurel water: cloths wetted in cold wash to be kept constantly applied over the joint, and evaporation promoted, so as to lower its temperature.

11th. Slept after the draught; bowels well freed by the enema; pulse accelerated and full; experiences great comfort from the cold application to the joint, which is to be continued, and also the opiate draught at night; low diet.

12th. Restless during the entire night, and refers pain to the posterior and outer side of the arm above the wound; pulse full and bounding; skin hot. Ordered twelve ounces of blood to be taken at once from the arm, and when the bleeding had ceased cold again to be continued; also three grains of calomel, with a grain and a half of powdered opium, with the intention of acting as a direct sedative.

13th. He is better to-day; slept at intervals through the night; the character of the pulse materially altered; it is much softer; however, the pain in the arm, just above the wound, continues the same as on yesterday; there is a slight blush of inflammation over the point referred to. To continue the cold application. Bowels not free, and belly tympanitic. Ordered immediately a full terebinthinate enema, and afterwards a turpentine stupe over the abdomen; also

℞ Pulv. hydrarg. c. cret. ʒss.
Pulv. Doveri gr. xxiv. Ft. pulv. divide in chart. vi. sumat i. tertiis horis.

14th. Slept comfortably during the night; pulse quiet

and soft; bowels copiously freed, and tympanitis gone; the blush of redness and the pain above the wound removed to the posterior part of the joint; imperfect suppuration established, so for the first time removed the straps of adhesive plaster, but without lifting the limb from the pillow or stirring it from the position which it has maintained from the very first. I slipped a small perforated pad under the elbow, so as to receive the internal condyle and avert stripping, placed a small light poultice over the seat of the wound, a few straps of adhesive plaster being first applied, not with any increased tension or straining of the lips of the wound, but with the object of supporting the soft parts, which for a short distance above and below the joint had united by first intention. Synovia mixed with imperfect pus was freely discharged from between the bones on the removal of the dressings. Cold was still applied to the shoulder and upper half of the arm, so as to keep down the temperature. To continue the powders as on yesterday.

15th. Free from all pain in the joint; suppuration fully established. To continue one powder morning and evening, to repeat the poultice over the wound, and cold at intervals over the shoulder and arm.

16th. Slept well; pulse very soft and feeble; wound discharging pus freely and synovia in abundance on the least pressure. The poultice to be continued over the wound, and the cold applied as before; to take only one powder at night, lest the depressing effects of the mineral might too far debilitate.

17th. Slept well; arm free from pain; on lifting the adhesive straps from the wound, the granulations were remarkably fungoid, transparent, and projecting several lines over the edges. To continue the powder at night, the poultice over the wound, and the cold over the shoulder and arm.

18th. This morning the limb was free from all pain; a large flow of synovia and pus from the joint; at three p.m. he was suddenly seized with darting pain in the joint of a very severe character, and coming on without any assignable cause. Ordered at once six leeches to be applied above the joint, and afterwards warm stupes to be assiduously kept to the entire limb; a full opiate at night.

19th. Has had little sleep, and refers great pain to the joint, darting up and down the limb. As inflammation most insidiously again threatened, it was prudent to increase the mercury. Ordered one of the powders three times in the day, a poultice over the wound, and cold to the shoulder and arm as before: to repeat the opiate at night.

20th. He had little sleep last night from pain in the part; the pulse is that of extreme irritation; the joint is suppurating very freely; little trace now of synovia. Ordered four leeches above the joint, and the entire limb to be enveloped in a warm stupe cloth; at the same time a light poultice over the wound.

Pil. hydrarg. gr. vii., sulph. quinæ gr. iv. Ft. pil. ii. sumat i. bis in die.

℞ Aquæ puræ,
Syrup. simp. āā. ʒss.
Muriat. morphiæ granum. Ft. sumat ʒi. 2ndis horis. For nourishment, beef-tea and bread.

Three p.m. Feels comfortable.

21st. Slept at intervals through the night, and joint not so painful; on pressure synovia mixed with pus very freely discharged from the joint. Ordered to omit the pil. hyd., and to continue the sulph. quinæ, two grains three times a day; to have the yolk of egg beaten up with boiled milk and a tablespoonful of spirits, also beef-tea and bread; to continue the morphia syrup as before, and the poultice to the wound.

23rd. Was seized again to day with acute pain on the outer side of the joint. At once applied four leeches, which relieved it.

25th. Pain relieved in the part; discharge of pus very free from the joint; he has had flushings and sweats for the last two days; made up the limb as before, evenly supported on pillows; stopped stupes, poultice, &c., and ordered an astringent ointment to the granulating surface, and a mixture with quinine and acid. Ordered for diet lamb chops, the yolks of two eggs beaten up with boiled milk and a little spirits, also a glass of port wine.

27th. Somewhat better. Continue everything as before.

July 1st. Is better in every respect; slept well; very little perspiration; discharge from the joint greatly diminished. To continue everything as before.

4th. Has gradually improved for the last few days. This morning placed the limb in a well-adjusted case made of gutta percha lined with wadding. It was so constructed as to preserve immoveable the forearm at a right angle with the arm, and retained by bandages. The arm thus made up was supported in a sling suspended from a framework over the bed, and the enfeebled creature was propped in the sitting posture by a bed chair. He experienced the greatest comfort from this arrangement. No motions of the trunk produced pain in the arm, it so readily waved backwards and forwards on the slightest impulse.

5th. Has had little sleep: fainted twice; pulse very feeble; the limb is quite free from pain, which he attributes to its new and easy position; all apprehension of hurting himself on moving in the bed is removed by the simple contrivance adopted. To get four ounces of wine, eggs beaten up with milk, chop, and a glass of porter for diet.

6th. He is better to-day; slept well during the night, and the pulse is stronger; the discharge from the wound is less. Reapplied dressings as before.

8th. He has derived the greatest benefit and comfort from the suspension of the limb; has never had pain in it since this mode was pursued. To continue wine, support, &c., as before; also the quinine mixture.

11th. He is now mending rapidly; the limb is only dressed every second day, and there is very little discharge from the wound. To continue everything as before.

15th. Going on most favourably; pulse quiet; no sweats; limb free from pain, and dressed every alternate day; had his clothes put on to-day; kept him reclining on the bed with the arm supported and suspended as before. To continue wine, &c.: ordered to day half an ounce of cod-liver oil three times a day, and to continue the quinine mixture.

17th. Wound nearly closed up; fungoid granulations all gone; anchylosis rapidly progressing; no discharge now from the joint; the limb supported as before in the gutta percha case, and though the patient is dressed and lying supported on the outside of the bed, the "weight of the arm" is so great that the sling suspended from overhead cannot be dispensed with.

22nd. Gaining strength very rapidly; so well did he feel to-day that I was enabled to place the limb in a sling suspended from his neck, and had him carried to a couch in the garden, the weather being very fine and mild. To continue diet and medicines as before.

31st. Within the last few days, he has rapidly gained strength, being now able to walk about the ward and into the garden; the wound just healed; all the textures round the joint are thickened from the results of inflammation; but considering all things, the most sanguine expectations could not have anticipated a more favourable result.

August 2nd. On this day he was dismissed cured, the wound being entirely healed, and the joint quite stiff.

September 20th. Since his dismissal from the hospital up to the present date, he has gained considerable motion in the joint, and which I have no doubt will yet be materially increased.

The details of the foregoing case are so essentially practical that I do not hesitate in placing them on record, in warm anticipation that they may stimulate the younger members of the profession to exertions equally as effectual to the saving of life and limb. Wounds of joints are at all times to be dreaded and watched with the greatest careful-

ness on the part of the surgeon, inflammation is so insidiously set up and progressive in its effects, the danger being considerably augmented if injury at the same time be inflicted on the articulating surfaces of the bones, as occurred in this instance. From the earliest period an attempt was made to bring about union by the first intention. After the hæmorrhage was arrested, the piece of bone projecting through the wound was carefully restored to its natural position, the cut surfaces placed in contact, and all retained *in situ* by a few strips of adhesive plaster. I returned the piece of bone to its place in preference to cutting it away, because it was closely connected behind by the attachment of the triceps muscle—an attachment which I considered sufficient to preserve its vitality. If the piece had been smaller and not so vitally adherent, I would have acted exactly as Mr. Lawrence did in a case almost parallel to mine. The case is given in the *Lancet* for May, 1846. The patient, a boy aged 11, was admitted into St. Bartholomew's Hospital, his right arm being caught between two cog-wheels connected with machinery in motion. He was admitted a few moments after the receipt of the accident. The integuments on the outer surface of the right upper extremity, from the middle of the forearm up to the insertion of the deltoid, were severely bruised and torn. A deep lacerated wound extended through the skin and muscles down to the elbow-joint, which was opened. The external condyle was chipped off from the humerus and held only by a few tendinous and fleshy fibres. There was considerable venous hæmorrhage, but the brachial artery not wounded. Mr. Lawrence removed the external condyle by severing with a scalpel the soft shreds which retained it. This case did well.

Another case very similar is given by Mr. Key, in which the integuments of the arm of a boy, aged 9, were severely torn. The elbow joint was laid open, and the internal condyle chipped off by a roller in motion. In this case the internal condyle was removed by Mr. Key, and the important articulation between the ulna and the humerus was destroyed; yet this case, too, did well.

If portions of bone be so far separated as to be connected only by a few tendinous fibres, they should no doubt be regarded as foreign bodies, and immediately removed, as their presence would only excite inflammation and prevent the healing of the wound until discharged by Nature.

In the management of McGill's case, the antiphlogistic treatment was fully carried out: general bleeding when the inflammatory fever was at its height; local detraction of blood by leeches on the supervention of *pain;* the gentle administration of mercury; cold applied so as to moderate the temperature of the limb, and soothing applications when suppuration was established, the constitutional treatment being modified according to the type of the fever present. There is one more point in the local management which I have left for special notice, and that is the suspension of the limb at a suitable height in a sling. This I cannot pass over without most warmly recommending. From the very period when I had recourse to this procedure in the foregoing case, many of the patient's annoyances were removed, and he began visibly to improve. Not only was the inflamed part placed in the most favourable position for its returning circulation, but the motions of the patient were not so constrained or prohibited he could turn partly to either side, and thus relieve himself from pressure. In this way the fatigue of lying was considerably lessened, and the irritation consequent on perpetual watchfulness removed; for on the slightest impulse the limb floated with its solid case suspended in the air. Again, when the patient was convalescent and lying dressed on the outside of the bed, propped up with pillows, the suspension of the limb in his emaciated and enfeebled condition was of the greatest value, for by it the weight was entirely borne.

CHEAP AND EFFICIENT ANTHELMINTICS.

By John Colvan, M.D., F.R.C.S.I., of Armagh.

A little female patient of about six or seven years old, who has been partly under my care for two or three months past, voided during that period eleven large round worms of the species "*Ascaris lumbricoides,*" one of which being so perfect, in every respect, I retained as specimen in my collection. The only medicines she used during the time specified were calomel, chlorid. hydrargyri, and rhubarb, the plain powder of the rheum palmat., the pill being two grains, and the powder ten grains. The pill was taken at bedtime, and the powder early next morning. The probable price of each dose was not more than two or three pence! There was an interval of from five days to seven between the doses. The child, so far from being weakened, improved greatly in strength and appearance, and is now so well as to be able to leave off the medicine for some time to come. I think had the medicine cost £1 each dose, and had some outlandish name assigned to it, it could scarcely have been more effectual.

Armagh, September 20, 1851.

THE PATHOLOGY OF INFLAMMATION AND FEVER.

By H. Freke, A.B., M.B., M.R.I.A., Dublin.

(Continued from p. 179.)

At the close of my last communication we were engaged in the consideration of the nature of what I have termed compound residual products in their relation to *simple* or *indivisible* organisms; such, for example, as that which I have named the nervous organizing atom. I am now desirous of making a few observations upon compound residual products in their relation to *compound* or *aggregate* organisms; such, for example, as the embryo of man. I am desirous, in other words, of calling my readers' attention to the nature of the relation which must, as I conceive, subsist between a compound organism, such as the human embryo, and the compound residual product, which is capable, and alone is capable, of arousing that organism to the discharge of its specific physiological function. The relation, in a word, which subsists between that embryo and what I have termed its *specific stimulus*, or the stimulus provided by Nature for calling into operation its physiological function.

I have already directed my readers' attention, in a general manner, to what I conceive must be the anatomic composition of that embryo, and have endeavoured to make it apparent (from the functions which it is called upon to discharge—namely, *to generate a number of distinct individual organized structures*); I have, I say, endeavoured to make it apparent that such embryo must of necessity be formed by the organic or physiological union of a *number of distinct individual organisms, or organizing agents;* I say must (as I conceive) *of necessity* be so formed, inasmuch as it is alone by an organism or organizing agent that any organized structure can by possibility be generated. To each of those organisms or organizing agents, I have (for reasons of which my readers are in possession) given the name *organizing atom.* And to the several organizing atoms comprised in that embryo (inasmuch as the function of those atoms respectively is to generate what we term nervous, vascular, muscular, glandular, &c., structure; that is, to generate the various organized structures which eventually constitute *man*) to the several organizing atoms, I say, comprised in that embryo, I have given the names respectively of the nervous, the vascular, the muscular, the glandular, &c., atom. These various atoms in combination constitute an *aggregate* integral, the function of which integral is *to organize.* And every aggregate integral possessed of such function, affords an example of

what I mean to convey by the terms *compound organism.** The compound organism which at present engages our attention, is that known to us by the name of the embryo of man.†

Such, I have attempted to make it appear, must be the composition of the organism which has been destined by Nature to generate *(when placed in the circumstances adapted for that purpose)* the various species of organized structure which are eventually to be found in the constitution of man. The question which is now about to engage our attention is this—namely, *What are those circumstances?* What are the conditions which Nature requires should be fulfilled before the function of that compound organism can commence—before that organism can *manifest* life?

It must be obvious to my readers from what has been already advanced, that this compound organism (or organizing agent) must of necessity remain inactive or dormant; that is, must remain in a quiescent or passive condition (like a body in which caloric is *latent*) till it has been presented with those requirements which Nature has made essential to every organism (whatever be its nature, whether simple or compound) before that organism can discharge its specific physiological function. My readers are already acquainted with the nature of such requirements, and are aware that one of the requisites essential to the performance of the specific function of every organizing agent is the presence of materials upon which that agent can confer organization; the presence, in a word, of materials which stand to that organizing agent in the relation of what I have termed its specific stimulus. Whence are those materials derived for the organism in question—namely, for the compound organizing agent which we term the embryo of man?

It must (as it appears to me) be from a source that is foreign to itself, and hence *we arrive at the necessity* (as I conceive) *for distinctions in sex*. One parent is required to generate the *embryo*, and another parent to generate a residual product, upon which that embryo can exercise its function.

In *one* parent of a vegetable, the various regenerated *organizing atoms* combine, and in union constitute an ovule, or the embryonic representative of the species; in *the other*, the various *stimulants* or *residual products* (required by those atoms in that ovule which demand to be *simultaneously*, at fecundation, called into operative action) unite to form that mysterious compound known to the botanist as pollen. In *one* parent of the organism, which we term the embryo of man, regenerated nervous, vascular, muscular, glandular, &c., *organizing atoms* (urged into union by the laws of organization and by the same laws deposited in that portion of the human mechanism appropriated to that end), constitute man's embryonic representative in the form of the contents of a Graaffian vesicle. In *the other*, elaborations and compound elaborations—namely, what I have termed *organized residual products* (of such high organization as may call into functional action the various atoms in that embryo, which, at the instant of conception, must spring into *simultaneous* operation), *in their accumulated form constitute man's regenerative sperm*. In this mystic secretion must be contained everything the embryo requires on which to manifest its earliest life. This residual product must, in a word, bear to the compound organism—the human embryonic type—the same relation which the inanimate elements of earth bore to the humblest conceivable of vegetations—the same relation that the liquor sanguinis of our blood bears to the fœtus and to man.

In the foregoing observations, in relation to the various atoms in the ovule and in the embryo which require to be called into action at the moment of fecundation, I have used the words "which demand to be *simultaneously* called into operative action," and which "must spring into *simultaneous* operation." I shall explain my motive for employing those words. My readers will observe, from what has already been advanced, that a striking and marked distinction (in the requisites for fecundation) must necessarily exist between one of the simplest or most humble species of organizing atom individually and alone and a *compound* organism composed of a plurality of atoms of different species, that is, of *different degrees of elevation in the scale of organization;* or composed of atoms some of which require the presence of *compound* residual products. I have attempted to make it apparent that the humblest conceivable vegetation is composed of but a *single individual* organism (namely, a solitary organizing atom), and that the *only* specific stimulus required by that organism on

* In the above paragraph I have endeavoured to illustrate, in conjunction, several of the statements which have already been advanced. Thus, for instance, I have in the first place defined an organism to be *an integral capable of manifesting an independent vitality;* and have divided organisms into *simple* and *compound*. Secondly, I have stated that the specific physiological function of every organism (whether simple or compound) is *to organize;* that is, in other words, *is to confer organization upon materials distinct and apart from those which form a portion of its own constitution*. And, finally, I have defined *living* to be *the act of being elevated in the scale of organization*. In the paragraph before us I have endeavoured to place in connexion illustrations of my meaning in these several statements. My readers have an example of what I understand by a *simple* organism in, for instance, what I have termed *a muscular atom*. By the term muscular atom, my readers are aware I mean *that organism which generates muscular fibre*. Now, what is the function of this muscular atom? It is *to confer organization upon fibrin;* it is to *raise* fibrin (though already highly organized) *still higher* in the scale of organization; it is, in a word, to *raise* fibrin to the condition of muscular fibre. Such is the function of the muscular atom (a subject upon which we shall enter more fully in a future communication), and it is obvious that the fibrin (upon which that atom is designed to confer increased organization) is distinct and apart from that atom. In other words, it is obvious that the *atom* and the *fibrin* are *two distinct entities;* the former being an *organizing agent* which is about *to confer* organization; the latter being an *organized mass* (viz., a residual product) which is about *to receive* organization—that is, whose organization is about to be *augmented*. It is scarcely necessary for me to call my readers' attention to the fact that *until* that muscular atom *has commenced* the discharge of its function, it cannot (though possessed of the vital or organizing influence), until, I say, it has *commenced* the discharge of its function, it cannot be said to *be living*, but remains in a *latent* or dormant condition. It is when, and when *only*, the fibrin is *in the act of being elevated in the scale of organization*, that the muscular atom and the fibrin conjointly can be said to be *living*. The same appears to me to be true of *all organisms*, and hence the propriety (as it appears to me) of defining *living* to be *the act of being elevated in the scale of organization*. I shall hereafter endeavour to show that the various atoms in a compound organism, though physiologically united (as, for example, the muscular and the nervous atom in the embryo), notwithstanding *live;* or, in other words, discharge their function of organizing, *independently* of each other. Such is what I mean by the terms *simple* organisms, and such is what I conceive to be the nature of their function. In the human embryo my readers have an example of what I understand by a *compound* organism, the function of which forms the subject of the present communication.

† The above is not the utmost limit to which (as it appears to me) our analysis of the anatomy of the human embryo (&c.) can be carried. We can, as I conceive, pursue our inquiries still further, and determine with the strictest precision the number of *varieties* of organizing atom which must be contained in that embryo. Thus, for example, we know that two varieties of nervous and of muscular atom must exist to generate the two varieties of nervous and muscular structure, known as voluntary and involuntary. We further know that such embryo must contain a considerable number of varieties of glandular atom; all of which can be determined with the greatest degree of precision. And so on of all its other components till we have arrived at the absolute composition of that embryo. In one of my future communications I shall attempt to point out in what manner, I conceive, we may possibly attain to a certain amount of knowledge as to how the various atoms in that compound must be relatively arranged or disposed.

which to discharge its specific physiological function (of conferring organization) is certain species of *inorganic or mineral matter*. When this specific stimulus is present (with the additional presence of its *incidental* stimulus, and the other requirements, such as temperature and moisture, &c.), when, I say, *this* specific stimulus is present, that organism, or organizing atom, can *complete* its *entire* physiological function without the presence of any additional requirement—without, in a word, the presence of any *organized* residual product. Hence it is apparent that *this* organism, or organizing agent, can have no necessity for a *plurality* of parents. A *single* parent is required to *regenerate* that *atom;* but no parent is required to generate an *organized residual product* to stimulate the *offspring* atom to the discharge of its physiological function. The residual product (if I may so term it) required by that offspring atom for that purpose, has been already provided by Nature in the mineral or *unorganized* world. Hence that atom has no necessity for an *organized* residual product—hence it has no necessity for *a parent to generate such product*.

But such is far different with regard to *compound* organisms. Such must of necessity be far otherwise with respect to organisms which comprise in their composition *different species* of organizing atom; such, for example, as the embryo of the loftier vegetations, of animals and of man. I shall endeavour to convince my readers of this distinction, and to show wherefore, in the case of *such* organisms, there is (as it appears to me) a necessity for a plurality of parents.

I attempted to point out (in the case of the supposed organism which I selected as illustrative of the nature of a *compound* organism—namely, that which I supposed to be formed by the union of three individual atoms selected from the first three species of organizing atom in succession), I attempted, I say, to point out the nature of the relation in which the three *simple* atoms (comprised in the composition of that *compound* organism) stood towards each other. That relation, I endeavoured to make it appear, was the following—namely, that the first or simplest of the three atoms in the compound, formed or generated *(out of inanimate or mineral matter)* an organized residual product which was capable of calling into operation the function of the second species of atom; and that the second species of atom formed or generated *(out of the organized residual product prepared for it by the first)* a more highly organized residual product which was capable of calling into operation the function of the third species of atom. It is hence clearly obvious how, by means of inanimate or mineral matter, *exclusively* and *alone* (that is, without the additional presence of any other specific stimulus—without the presence of any *organized* residual product), it is, I say, clearly obvious how, by means of inanimate matter, exclusively and alone, the three atoms in that supposed compound organism could *successively (but not simultaneously)* be called into physiological operation.

That is, when the first species of atom had *completed* its function—namely, had generated an organized residual product out of inanimate or mineral matter, *then*, and *not till then*, could the function of the second species of atom *commence;* while it is not till a *still later period* (namely, not till the function of the second species of atom had, in like manner, been *completed)* that the third species of atom in that compound could *commence* its physiological function.

It thus becomes obvious that if mineral matter, exclusively and alone, be supplied as its specific stimulus to that compound organism, the component simple organisms of that compound can only be *successively* (and not *simultaneously)* called into physiological action.

Now, if it be required that *the three atoms* in that compound organism should *simultaneously* discharge their physiological function from the *very commencement* of the functional action of the compound; that is, if it be required that the first, second, and third atom in that compound should *all three at the same moment* commence the performance of their function, it is obvious that inanimate or mineral matter, exclusively and alone, would be utterly incompetent to bring such end about. Inanimate or mineral matter is *only* competent to call into operation the function of the *first or simplest* of those three atoms, and could be no more competent to call into operation the physiological functions of the second and third species of atom in that compound, than it could be competent to call into operation the physiological functions of the various atoms comprised in the compound organism man.*

If, then, I say, it be required that the second and third species of organizing atom in that imaginary compound organism, should commence the discharge of their physiological function *at the same moment* that the function of the first species of atom is commencing, how could this end be accomplished? *It can alone* (as it appears to me) *be accomplished through the agency of a plurality of parents.* I shall endeavour to explain myself more clearly. The *three* atoms are, we suppose, required to commence their physiological operation *simultaneously;* hence it is obvious that *two organized* residual products (namely, one to call into operation the function of the second species of atom in the compound, and another to call into operation the function of the third), it is, I say, obvious (as it appears to me) that *two organized* residual products must necessarily be derived from *some source or other*, to call into operation the physiological function of the second and third species of atom in the compound. It is, in a word, obvious (as I conceive) that before this imaginary compound little organism can *commence* the discharge of its physiological function, it must be presented with *a compound organized residual product*, derived from some source or other, which can stimulate (that is, call into action) its second and third species of atom, inasmuch as we have supposed that those atoms are required to be in operation *at the commencement* of the function of the compound. Now there is *one* source, and *but one source alone*, from whence an organized residual product *can by possibility* be derived—namely, *it must be generated by an organism or organizing agent.* Hence the necessity (as it appears to me) for an organizing agent to generate a compound organized residual product which can call into operation the function of the first and second species of atom in that organism. Hence, in other words, the necessity for a *second parent* to generate *that* whereon this compound organism can *commence* the discharge of its physiological function—can *commence* the *manifestation* of vitality.

That such supposed state of things is what *actually is required* with regard to the component organizing atoms comprised in the constitution of the embryo of the loftier vegetations of animals and of man, I shall now endeavour to make apparent to my readers.

Let us in place of the supposed compound organism which we have just been contemplating (namely, that which we regarded as composed of three *imaginary* atoms, the function of which three atoms we supposed it was required should commence *simultaneously*), let us, I say, in place of this supposed compound organism, substitute the compound organism known to us as *the embryo of man.* With the composition of *this* organism we have already made ourselves acquainted, and *its* components are no *imaginary* atoms. The nature of that compound and the nature of its function are known to us, and consequently the nature and function of its components. And what do we know with regard to the nature and function of this

* Present inorganic or mineral matter, exclusively and alone, to the compound organism man, and what is the result? The result is this—namely, that that organism *ceases to discharge its physiological function.* And what is the cause of this result? The cause is simply this, that *no organized residual product* has been presented to the various organizing atoms in that compound organism upon which those atoms can discharge their physiological function of conferring increased organization (that is, in other words, their physiological function of generating (out of matter *less highly* organized) the various organized tissues in man), and consequently the function of those atoms must of necessity cease.

compound and of its components? We know the following two facts—namely, 1st. That this *compound* organism is composed of a number of *simpler* organisms whose functions respectively are to generate what we term vascular, glandular, muscular, nervous, &c., structure. And 2nd. We know that certain of those simple organisms require the presence of a *compound* organized residual product to enable them to generate the required organized structure. So much (as it appears to me) we know as regard the nature and function of the several organizing atoms comprised in the composition of that compound.

But do we know anything as regards *the period* when it is required that those several atoms should respectively *commence* the discharge of that function—should *commence* the generation or development of the various structures they are respectively called on to generate? Do we, in other words, know anything in relation to *the time* when it is requisite that the development or generation of the various tissues found in the *fœtus* of man (that is of vascular structure and of glands; of muscular structure and of nerves; of osseous tissue, &c. &c.), do we, I say, know anything as regards *the time* when it is requisite that the development or generation of these various tissues *should commence* in the *embryo* of man? I conceive we do. I conceive we know *this* to be requisite—namely, the generation or development of *several* of those tissues must (as I conceive) of necessity commence *simultaneously*, and that at the *commencement* of the functional action of the embryo. For were it otherwise, Nature's design in the formation of that embryo could not (as it appears to me) be accomplished, but such design must, as I conceive, of necessity be frustrated.

For what was Nature's design in the formation of that embryo? It was that it should generate Man, *between the various tissues or organs of which man (when developed) there should exist a perfect unity or harmony of function.*

Now, if the function of *several* of the component organisms (contained in that embryo) *had not* commenced *simultaneously*, and that at the *commencement* of the function of the embryo, it appears to me that the *relation* (now observed, and which must of necessity be preserved, with regard to their relative stages of development)—it appears to me, I say, that the relation in *development* between several of the organized structures found in the fœtus of man could by no possibility exist. The result (as it appears to me) must of necessity be this—namely, that when the development of that fœtus had arrived at completion, the *utmost confusion* must prevail between the functions respectively of its several organs; for no harmony could be preserved between the *functions* of its structures, if none had been observed between their *development*. In place of the *symmetry* now recognizable throughout organic creation, we should everywhere encounter *deformity*. For the slightest disturbance of this balance of relation (between the development respectively of the several tissues of the embryo) must give origin to some form of congenital defect.*

If, then, it be required that at *the commencement* of the functional operation of the embryo of man (which we have already seen generated by *one* parent) several of its component organizing atoms (some of which require the presence of a *compound* residual product) should be *simultaneously* called into operative action, there is but one means (as it appears to me) whereby such end could be accomplished, and that means is (as I conceive) the following—namely, *another parent* must (as I conceive) have pre-existed to generate such *organized residual products* as Nature has made essential to the performance of the function of those several atoms.

(To be continued.)

Paris, August, 1851.

* I should gladly dilate upon a topic which to me appears to be one of extreme physiological interest, and should be desirous of attempting to point out to my readers the several structures in the fœtus, the generation of which (it appears to me) must necessarily commence simultaneously at the commencement of function of the embryo. I should be also anxious to lay before my readers what I conceive to be the nature of the various structural changes which must (as it appears to me) of necessity take place during the period of fœtal existence. The present, however, would not be the appropriate place for so doing. Having now ventured upon an investigation of equal importance, I shall look forward to entering at some future period upon a detailed inquiry into the subject of embryology. Thus much upon the subject I have been induced to introduce into this paper, merely in order to enable me to lay as clearly before my readers as possible the nature of the relation which I conceive to exist between an *organism* and what I have termed an *organized residual product.*

PROFESSOR BENNETT OF EDINBURGH ON CARBONACEOUS LUNGS.

Thomas Wilson, æt. 38, collier, from the Oakley Mines near Dunfermline, was admitted into the Clinical Ward 26th July, 1851. He states that he has been employed about coal mines for the last twenty-four years, during the principal part of which he has been occupied in blasting rock for the sinking of pits, using large quantities of gunpowder daily. He is much exposed to cold and wet in this occupation, working almost constantly with wet feet, and frequently with the whole of his clothes drenched. During the laying open of a new surface for the working of coal, he has often worked in an atmosphere barely capable of supporting the combustion of the miners' lamps; he has observed this particularly when working iron stone. Notwithstanding, it was only about seven months ago that he began to be troubled with short dry cough, and difficulty of breathing. He continued to work till about four months ago, when the cough became more severe; he had much dyspnœa, and frequent profuse perspiration, especially at night. Two weeks after this,—that is, about fourteen weeks ago,—he was laid up from work; and about the same time, while under treatment, he began to spit much, and observed that the expectoration was of a deep black colour. The change was so sudden as to alarm him considerably.

On admission, the chest is of large dimensions and well formed. On percussion, there is slight comparative dulness on the left side of the chest over the upper half in front; and there is also appreciable dulness over the same extent on the same side posteriorly. There is complete resonance on the right side anteriorly and posteriorly.

On auscultation, for some inches below the clavicle on the left side, the inspiration is rough and harsh, and there is prolongation of the expiration. Lower down on the same side, there is also fine moist râle, and the vocal resonance is somewhat increased. On the right side there is loud pealing vocal resonance both anteriorly and posteriorly; it is particularly loud in front immediately below the clavicle, but there is nothing abnormal to be detected in the respiratory sounds. The sputum is in considerable quantity, adheres tenaciously to the bottom of the spit-box, and is of an intense black colour. On being placed in water, a small portion of a lighter colour swims on the surface, but the greater part sinks immediately. On being allowed to stand for a little, the supernatant water becomes nearly clear, the dense black mass remaining at the bottom of the dish. Acetic, sulphuric, and nitric acids, and also aq. potassæ, though boiled with the sputum, do not in the least affect its colour.

On placing a small portion of the sputum below the microscope, many of the epithelial cells are seen loaded with the black carbonaceous matter. In some of them, the nuclei are evident, the matter being deposited between them and the cell walls; in others, the nuclei are quite concealed. In other parts of the field, all appearance of cells is lost, and nothing but apparently homogeneous black masses are seen. Some of the cells may also be seen ruptured, and the black contents poured out.

The expansion of the chest is equal on both sides. Breathing is equal and unembarrassed while he is sitting

or lying in bed, but on using much exertion, it becomes short and difficult. There is some cough, but it is not very troublesome. States, that at the commencement of his illness, he could not lie on his left side; but at present he can lie in any position without uneasiness.

The other systems are quite normal. Has good appetite, no sour or unpleasant taste in his mouth. Bowels are regular at present, and are generally so; has never had diarrhœa. Does not sweat at night, or when he is not employed at his work. Pulse during examination was 88, soft and full; during his stay in the house, has averaged about 76. He was ordered an expectorant mixture; and during the last fortnight he was in the house, he had three tablespoonfuls of cod-liver oil daily. He went out by his own desire in August.

Commentary.—The physical signs existing in this case leave us in little doubt that there was considerable condensation at the apex of both lungs. This was indicated on one side by considerable dulness on percussion, and on the other by pealing vocal resonance. It is true, the resonance in this place was unaccompanied by any change in the percussion note, a circumstance that may be caused by the existence of slight emphysema counterbalancing the increased limits of the pulmonary tissue. The history of the man's case, the nature of his employment, and the black sputum, at once indicated to us that this condensation was owing to the accumulation of carbonaceous matter in the lungs, a disease which is peculiarly apt to occur in coal-miners, the moulders in iron and copper, and a few other trades. From the circumstance of its being very common among the colliers in the neighbourhood of Edinburgh, the disease has been thoroughly studied here. In the first case that was recorded by Dr. James Gregory, the black matter was analysed by Dr. Christison, and shown by him to consist of pure carbon or lamp black, a result confirmed by every subsequent writer. The papers by Dr. William Thomson, inserted in the XX. and XXI. Vols. of the Medico-Chirurgical Society of London, contain a mass of important information concerning this disease; and in a series of communications by the late Dr. Mackellar, inserted in the *Monthly Journal* for 1845, you will find numerous facts and opinions regarding it, the result of long and extensive practice among the colliers of Haddingtonshire.

On examining the lungs of those who die labouring under this disease, they are found to present a deep black colour, which is most intense towards their apices. On section, the pulmonary tissue yields on pressure a copious black inky juice, which stains all surrounding objects, attaches itself to the inequalities on the skin of the hands, and insinuates itself under the nails like fine black paint. At the apices of the lungs, the pulmonary tissue is generally more or less condensed, and the black matter thicker, and often of the consistence of putty. In advanced cases, ulcerations and cavities exist, exactly resembling in all their characters those of phthisis; with the exception, that no tubercle can be discovered, and that the whole is of an intense black colour. Occasionally black indurated and gritty masses can be felt and dug out, which in some rare cases, present a slight crystallized structure like coal or crystallized carbon. The morbid anatomy of the disease will be best understood by carefully examining the preparations I now show you from the University Museum.

On placing some of the black fluid squeezed from the lung under a microscope, and examining it with a power of 250 diameters linear, it is seen to consist of a multitude of black molecules of extreme minuteness floating in a liquid. Here and there may be observed cells, similar to those previously described as existing in the sputum, more or less loaded with similar molecules of black matter, on which the strongest chemical re-agents produce no effect whatever.

When we endeavour to investigate the pathology of this disorder, we are met with a host of difficulties. Does it originate from the inhalation of carbonaceous particles floating in the atmosphere, or is it the result of a secretion of carbon in the pulmonary system itself?

The principal fact on which the first opinion rests, is the frequency of the disease in colliers, and in moulders of iron and copper. Yet it is curious, that whilst it is common among the workmen of some coal pits, it is unknown among those employed in others. For instance, it exists to a great extent among the colliers of Fife, Haddingtonshire, and Midlothian, but is unknown at Newcastle, Paisley, or Alloa, although the dust and powder is as finely levigated in one place as in another.

There is another curious fact connected with the disease in coal miners,—viz., that those engaged in working at what is called the *coal* wall, and in sifting or transporting the coal, are little affected; whilst those who work at the *stone* wall, are peculiarly liable. This working at the stone wall, consists in blasting the rock by means of gunpowder. Hence the prevalence of black deposits in the lungs has been by some not so much attributed to the dust of coal, as to the smoke of the explosions, or of the lamps carried by the miners, confined as it is in narrow passages, where little ventilation exists.

Even this explanation has difficulties; for it has been proved, that in some mines, where blasting is carried on very extensively, and where there is much coal dust, it does not exist at all; and hence it has been supposed that there are some kinds of stone which disengage gases, or the working among which is much more deleterious than others. Thus Mr. Philp of Aberdour, who has had great experience in this disease, in a communication he made to Dr. Thomson, says,—"In working at stone work, that is, in sinking pits and driving mines of communication, the workmen are exposed, in an imminent degree, to the influence of the impure air; for, besides working in a confined space, and in a *cul de sac*, where the ventilation is very imperfect, there is also a considerable exudation of the carbonic acid gas from the fresh cut surfaces of the minerals. In this impure air they continue to work for many hours daily, for some months, their operations being frequently carried on several yards in advance of where their lamps will burn." In another place, he says—"Those pits and mines which have been noted for the impurity of the air, have given origin to the greatest number of cases."

Again, Mr. Steele of Craighall says, he considers the disease to be caused by running mines in stone, and working in impure air. He says again,—"A principal reason is, that the stone contains some poisonous matter, which is probably of a metallic nature, as the workmen complain of it exciting a styptic and metallic taste in the mouth. A mine was carried across the strata in the Niddry estate, the finishing of which required a number of years. Six or eight of the miners employed in it died; several were obliged to leave it, and only one of those who commenced it was able to work in it throughout, and lived to see it completed. There was a particular stone in this mine, which was repeatedly met with, and to which the miners gave the name of arsenic, which was found highly pestiferous. Its exact nature I am not acquainted with. In a stone mine, run some years ago in the Newbattle field, a great many men died,—the average length of time each of the miners employed in it lived being about two years. The mortality was ascribed to the nature of the stone."

The facts connected with this peculiar black colouring of the lung, leave it therefore undecided whether it be owing to the inhalation of coal dust, the smoke of gunpowder and oil lamps, or carbonic acid gas, entering the lung. Is the powder deposited directly and primarily in the minute tissue of the organ, or is the carbon deposited secondarily, and by a process of secretion, from the blood?

Before we can answer these questions, there are two other series of cases, which it is necessary to take into consideration. 1st. Persons have been known to have the black spit, and black infiltrated appearance of the lungs, with caverns, without ever having been in a coal mine, or exposed in any way to gunpowder smoke. Several such cases are given in the paper of Dr. W. Thomson. One of these is by Dr. Brown, now superintendent of the Dumfries Lunatic Asylum; another, by the late Dr. Moir of Musselburgh. The subject of this last case was never ex-

posed to noxious vapours, unless it might be *carbonic acid*, as he was the proprietor of an extensive brewery, and in the daily habit of inspecting the tun-rooms, the large vats in which overflow with that deleterious gas. Another case was observed by the same gentleman, in the person of a coachman, where, after death, the lungs were found to contain collections of an inky or tarry fluid, which stained the fingers, as if with soot or charcoal. A fourth and similar case, in a woman, is related by Dr. Veitch. In none of these cases were the individuals exposed to the fumes of smoke, or coal dust. I have myself seen several such cases; in one especially, a cyst in the bronchial gland existed, about the size of the human eyeball, filled with a black inky fluid.

2nd. M. Guillot of Paris has brought forward another series of cases in old persons. He is physician to the hospital for aged people, and says there is scarcely an individual of advanced life who does not present the carbonaceous deposit in the lung, generally most marked at the apex. The carbon often exists in crude masses, obliterating the vessels and bronchial tubes. I have also seen many cases of this kind, and there can be no doubt that the longer we live, the more carbon is deposited in the lungs. In infants, as is well known, these organs are of a light pink colour, and they become more gray and of a deep blue or black tint as life advances.

What are we to conclude from these cases? The black matter in all of them, when chemically examined, is undoubtedly free carbon, and is distinguished from the similar occasional results of chronic pneumonia, and changes of the blood by the action of chemical agents. Dr. Pearson thinks that we are always insensibly breathing an air more or less loaded with smoke, the results of combustion, and other impurities; and that this of course accumulates the older we get. If this opinion were true, it should be more common in persons who inhabit densely inhabited and manufacturing towns, as London, Liverpool, Manchester, or Glasgow. Yet we do not find this to be the case. The air in Paris is remarkably pure, the fires of manufactories are few, and yet there, according to Guillot, it is common.

On the other hand, should we conclude that it is formed internally by a chemical process, in all cases? If so, must we ascribe it rather to the inhalation of carbonic acid gas, than to carbon in a minutely divided state, inspired from without? In the present state of our knowledge, we cannot answer these questions with any exactitude.

Another point of great interest is the apparent antagonism of carbonaceous deposits with tubercle.

We frequently find the black lungs of colliers to contain small or large ulcerated cavities, with bands crossing them; but we rarely find tubercle. In one or two cases chronic tubercle has been found; but it does not appear that the caverns filled with black matter in the miner are owing to tubercle. Such is the analogy existing between these cavities, and the symptoms they occasion, however, that the disease has been named "black phthisis" by several persons. Some have supposed that tubercular phthisis is first set up, and that the carbonaceous deposit is then insinuated among the textures and ulcerations. By others, and especially by the late Dr. Mackellar, it is maintained that there is never tubercle in these cases, and that ulceration is entirely owing to the accumulation of masses of carbon which are expectorated. I have carefully examined several lungs in various stages of the disease, but have never been able to satisfy myself of the existence of tubercle. The difficulty of the investigation, however, is very great, for it is probable that, did a tubercular exudation exist, it would be so impregnated with the carbonaceous matter, as not to be recognizable even under high powers. On the other hand, the bronchial tubes are frequently loaded with purulent matter of the usual appearance, but which, instead of presenting pus-corpuscles, is loaded with particles closely resembling those found in softened tubercle.

Guillot has alluded to the well known fact, that in old persons who present traces of tubercle, the cretaceous concretions are always surrounded by black matter. He thinks that the carbonaceous deposit compresses the capillaries which immediately surround the tubercle, prevents its further exudation, and so induces cure. But this is by no means invariable. Still it is an undoubted fact, that the black matter, like tubercle, always exists in greatest proportion at the apex, and the rarity of recent tubercle in combination with it, leads us to suppose that it exerts a peculiar influence on tubercular deposits. I have also seen black matter surrounding tubercle of the peritoneum, but in this situation it has not been free carbon, for long immersion in spirit has caused the disappearance of all colour.

So far as my observations have yet carried me, no difference is to be determined structurally between the pigment of melanosis and that of the disease under consideration. Some cells spit up by the miner, containing black granules, exactly resemble those in melanic cancer. On the other hand, there is a marked difference in the chemical constitution; as in the one, the black pigment, whatever be its nature, is fugitive, and removeable by chemical acids; in the other, fixed, and unchanged even under the blowpipe. Hence all black deposits may be divided into two classes; to distinguish which we may call one class by the name it has so long borne,—viz., "*melanotic*," and the other, from its chemical composition, "*carbonaceous*."

With regard to the treatment of individual cases of black phthisis, there is little to be said. The disease, once established, does not admit of cure by art; and it is a curious fact, that a man may work in a coal mine for many years without the black spit; but when it comes on, even should he leave the mine immediately, he will continue to expectorate carbonaceous matter ever afterwards. Of this the case before us furnishes us with an example, and the circumstance is one which furnishes a strong argument in favour of those who contend for the disease being dependent upon a secretion rather than a mechanical deposition of carbon. A palliative treatment, guided by the nature of the symptoms and strength of the constitution, is all that is admissible. The only means of preventing the disease seems to consist in ventilating the mines where colliers work, or adopting means of carrying off the fumes to which the moulders of iron and copper are exposed. Such prophylactic measures are equally called for, whatever theory of the nature of the disorder shall ultimately be proved to be correct.—*Edin. Monthly Jour.*

ON THE SPECULUM VAGINÆ.

By Robert Hull, M.D.

If rumours be well founded, it is high time that the fathers, brothers, *husbands*, in Great Britain should rise, with indignant protestation, against the abuse of the *speculum matricis*. Let them refuse to permit their female relatives to be treated by men, with whom the *speculum* is the *vademecum*. Let every British gentleman be sure that this disagreeable practice be *needed* in the peculiar case; and let him demand, if it be asserted that speculation, cautery, &c., be indeed required, that a *second* opinion be obtained, and a personal consultation forthwith held. Why should it be *assumed*, that in cases of vaginal any more than rectal disorder, turpitude, love of lucre, falsehood, are impossible? Everybody knows that the *rectum* bowel has been the pretended cause of most indirect conduct, most direct swindling. If a man cannot gainsay a surgeon who tells him that his disorder results from stricture of the *rectum*, how can a sterile woman refute an accoucheur who tells her that she labours under constricted or ulcerated *os uteri*? If a medical man *be* dishonest, how can the poor dupe detect him?

What scope for an unprincipled man—what boundless scope, when it is considered how anxious married women are to breed—is there for knaves to assure them that they can make them prolific!—that with a *speculum* they can see the cause of their sterility—that with local applications they can remove it!

How easy for a crafty doctor to persuade an unhappy lady that her *os uteri* is closed, and that he must dilate with instruments to give access to the cavity of the womb!

although he knows that not only her *os uteri*, but the vagina itself, may be closed, so far as the conceptive portion of generation is concerned.

How perturbed the sleep of that man ought to be, who profits daily by such a figment; and this to the misery, wounded feelings, painful exposure of chaste English gentlewomen, as innocent as credulous! Are not the secret chambers of such a doctor, where women's wombs are impaled with bougies, more hellish, if this be possible, than the recesses where men sit daily with bougies impacted without necessity in their fundaments?

If women are to be thus maltreated—if such nonsense as occlusion of the *os uteri;* if still absurder nonsense, as occlusion of the Fallopian tubes, be promulgated for the pathology of barrenness—why do not the Royal Colleges of Physicians or Surgeons interfere? Why do they not summon such practitioners, and say to them—"Sirs, either you believe that sterility depends upon occlusion of wombs and tubes, or you do not. If you believe this pathology in the middle of the nineteenth century, you degrade our learned institutions by your foolery. If this be not your creed, but you find it lucrative to gull ignorant, credulous women, you still more disgrace our honourable corporations, and we sever the connexion." Is it possible that fellows who promise fecundity think that by manual irritation of the textures, by instrumental irritants, they can bring on the desired conceptive action?

The holding forth to barren ladies that they can be cured if they will only consult Dr. P. or Dr. Q., Dr. R. or Dr. S., is as much empirical as if these worthies paid for barefaced advertisements in the public journals; and they had best at once take to business in this line. For they well know that there is no specific remedy for the barren state; that their beastly *speculations* can produce moral mischief to an awful extent,—physical benefit none; that all that can be done is maintenance of the general health; that medical science hath never reached beyond *this;* that interfering, and the creation of anxious ideas, tend to augment the evil; that the more a woman thinks about this mysterious process, the less chance she has of undergoing it; that the peasantry, and working females in general, are prolific in proportion to their insonciance—nay, in proportion to their wishes *not* to conceive. Anxiety to secure heirs for wealth, for titles, seems to prevent the cherished object.

How is it that in past times uterine and vaginal disorders were treated with as much success as since the era of *speculation?* Nay, were they not treated with more efficiency? For if indeed so much uterine disease exists, as the fashionable diagnosis would imply, uterine maladies are less prevented than formerly, less tractable when they do occur. But I do not believe in this deteriorated state of things, unless women's fears produce morbid physical actions,—unless ordinary affections of the generative structures are magnified into malignity by the wretched mind.

In every direction, one hears of ulcerated vaginæ—of congested wombs—of *specula* wherewith to see the mischief—of lunar caustic applied regularly—of leeches applied to the interior parts. Boys fresh from the hospitals arm themselves with these bestial weapons as freely as with the stethoscope, Even women, brought to believe this practice necessary, send some such message as this:—"Mrs. T. requests a call from Dr. V., and that he will bring his *speculum* with him." Doubtless Mrs. T. thinks that she labours under a morbid uterus, since almost all her acquaintances so suffer *nominally*.

But is simple ulceration, simple abrasion of the vaginal membrane, so dreadful that the indecent *speculum* is required? If the substance of a womb or of its cervix be not involved, is lunar caustic with *manual* application required? If they *be*, can such superficial cautery suffice? For me, I doubt the diagnosis so frequently pronounced. I have been unable always to see the breach, which the *speculator* hath asserted; and if the abrasion be not visible by the medical eye, can it be detected by others? Yet I have heard of a practitioner's requesting a patient's companion to peep through the tube, and convince herself of the disease of her friend!

It is much to be hoped that physicians will not consider the speculum vaginæ as *their* instrument, any more than the sound for the urinary bladder. It is surely and solely the peculiar province of the physician-accoucheur and the surgeon-accoucheur; and whilst it is most desirable that the legitimate *speculators* should avoid the *metroscope* as much as possible, it is to be deprecated as unprofessional if any but they should use it at all. But if a pure physician doggedly would, after all, claim a right to *speculate*, may he act upon his discoveries? May he manually leech, may he manually cauterise? and if he does, is he not, to use a vulgar expression, unprofessionally "poaching on the manor of the surgeon?" There are some men—there are many men—in our profession, whom no motives can sway save the selfish and the pecuniary. To such persons it is necessary to declare that their doings are not so concealed as they may fancy; that names are mentioned in the provinces, of *speculant* metropolitan practitioners, with vehement and increasing indignation; that country and family surgeons are about to *select*, with manly determination, the persons whom they will permit their patients to consult,—about to prohibit (and let me warn the delinquents that they *can)* from the *speculigerent* worthies—about to direct, with exclusive precision, and without mistake, to respected, venerated accoucheurs, whose unsullied career reminds us of bygone days.—*Med. Gaz.*

In the whole course of our editorial labours none of our numberless delinquencies raised such a storm of virtuous indignation, or caused such a down-pouring of invective and threats, as an allusion in similar strain to the above, made in one of our publications. It seems, however, both from this, and the commonly expressed opinions of a large majority of our profession, that we were right, and that the consequences we predicted have really followed the practice of which we complained. It was said at the time that our sarcasms were levelled at one individual, who almost monopolized the new contrivance, and perhaps they were; but however applicable the above may be to his case, it is evidently not directed to it in particular. In fact it is very generally believed that unless the proceeding be more discreetly, perhaps we may say more honestly, conducted, much scandalous insinuations must inevitably follow.

ON EXTRACTUM CARNIS.

By Dr. Beneke.

Dr. Beneke gives the following recipe for making beef-tea:—"One pound of lean beef, free of fat, and separated from the bones, in the finely chopped state in which it is used for beef sausages, or mince-meat, is uniformly mixed with its own weight of cold water, slowly heated to boiling, and the liquid, after boiling briskly for a minute or two, is strained through a towel, from the coagulated albumen and fibrine, now become hard and horny. Thus we obtain an equal weight of the most aromatic soup, of such strength as cannot be obtained even by boiling for hours from a piece of flesh. When mixed with salt, and the other usual additions by which soup is usually seasoned, and tinged somewhat darker, by means of roasted onions or burnt sugar, it forms the very best soup which can in any way be prepared from one pound of flesh." He states that he has often used this beef-tea, and from what he has experienced he cannot recommend it too strongly. In many diseased states it is not to be replaced by any other sort of food or remedy. He has administered it in scrofula and phthisis, especially in those cases in which derangements of the digestive organs were present, such as ulcerations, dyspepsia, tubercular deposits in the intestinal glands, &c. He has given it in the early and later periods of typhus, and to patients suffering from inflammation of the cellular tissue, and rapidly wasting away in consequence of the most abundant suppurations, and there cannot exist a more rational remedy than beef-tea, to com-

pensate the abundant loss of materials. He has finally given it in many other states which required a good nourishment by animal diet, and almost all patients who are convalescent from severe diseases are most beneficially influenced by it. He does not enter into a more accurate explanation of the effects of the beef-tea; it is self-evident that a substance, containing all constituent parts of the meat, both inorganic and organic, and not at all causing any exertion of the digestive organs to recompose into nutritive material, must be of such an effect as no other special remedy can be expected to manifest.

This being a fact, it appears to be most desirable, that the beef-tea, which the author calls *Liebig's beef-tea*, should be well known to every practitioner, and should be always given wherever the state of the patient requires a good animal, nitrogenous food. However, as he has often experienced, one meets in practice with many difficulties in having it prepared, or provided at all for the patients, especially in dispensary practice, where poverty appears with all its sad consequences and companions, and where so many cases occur, requiring a nourishing, strengthening treatment; in advising patients to take meat, beef-tea, &c., we hear them too often answering "we cannot afford it." In private practice, we find single persons confined to their bedrooms, with scarcely any assistance at all; perhaps we order them to take the before mentioned beef-tea, but it is beyond all possibility for them to have it prepared, as it requires some attention and carefulness. And even in family practice, it is necessary to describe each time the mode of preparing the beef-tea on the one hand, and questionable on the other, whether the attendants of the patient prepare it with that accuracy which is required for the accomplishment of our purposes. Hence, it appears as desirable as possible, to have an opportunity for easily providing patients of all classes with a sort of food and a remedy, which cannot be replaced by any other; and he therefore advises that the beef-tea be prepared at the chemists' and druggists' shops. It must be mentioned, that the above described beef-tea, when evaporated in a water-bath, and cooled afterwards, forms a brownish-yellow extract, and this extract, to which we may give the name of *extractum carnis*, should be prepared and kept for sale by chemists. In accurately following the above described method of preparing the beef-tea, the quantity obtained out of six pounds of meat may be evaporated to three ounces, and those three ounces, after having cooled, form the "extractum carnis." One ounce of extractum carnis is therefore equal to thirty-two ounces of meat, whence it can easily be calculated how much of it is required for providing a patient daily with the constituent parts of three, four, five, six, or more ounces of meat.—*Lancet.*

ON INFLAMMATION OF THE SYNOVIAL MEMBRANES OF JOINTS.

By Sir B. C. Brodie, Bart.

As to the constitutional origin of these affections, Sir Benjamin remarks:—"Inflammation of a synovial membrane may arise as a local affection, the consequence of a sprain, a contusion, or other mechanical injury. In other cases, various joints being affected, either simultaneously or in succession, it is manifestly the effect of a disordered state of the general system; and even in those instances in which the inflammation is confined to a single joint, a careful inquiry will generally satisfy the surgeon that it has had a similar origin. Indeed I must confess that, in proportion as I have acquired a more extended experience in my profession, I have found more and more reason to believe that local diseases, in the strict sense of the term, are comparatively rare. Local causes may operate so as to render one organ more liable to disease than another: but everything tends to prove that, in the great majority of cases, there is a morbid condition, either of the circulating fluid, or of the nervous system, antecedent to the manifestation of disease in any particular structure. Moreover, even in those cases in which a disease may be distinctly traced to some kind of mechanical injury, the character which it assumes depends as much on the state of the general health as on the injury itself. Thus we find a sprain of the ankle, in one instance, to be followed by no urgent symptoms, while, in another, a sprain not apparently more severe, is followed by intense inflammation, for the removal of which the most active antiphlogistic treatment is required."

In a great number of instances, the synovial inflammation is attributable to a gouty diathesis, evidenced by the existence of lithates in the urine, and according to Dr. Garrod in the blood; or to rheumatic inflammation, accompanied or caused by the predominance of lactic acid in the system (Prout). And the circumstance that such diseases show themselves in the synovial membranes of joints, rather than in the serous membranes which are nearly allied to them, is to be explained by the constant motion of joints, and generally speaking, by their liability to injury from their exposed positions.

Sir Benjamin insists in the treatment "of the necessity of regarding them as constitutional and not local affections." When the joint is greatly and distressingly distended with serum, it is recommended to make a few minute punctures, and apply an exhausted cupping glass, and as soon as pus is known to have been secreted, to make a free incision into the joint. He then says:—

"If it be a question whether a collection of fluid in a joint be purulent or otherwise, it is prudent, in the first instance, to make a puncture with a grooved needle. If it prove to be purulent, a free opening should then at once be made with a lancet, in a depending situation. It is important that this operation should not be long delayed, lest the matter should make its way out of the joint in other directions, and form irregular and circuitous sinuses among the neighbouring tendons and muscles. It is equally important that the opening should be sufficiently large to allow the matter to flow spontaneously, without it being necessary to have recourse to pressure on the joint. If afterwards there be reason to believe that there is still a lodgment of matter in any part of the joint or among the neighbouring soft parts, the original opening should be dilated, or the surgeon should avail himself of the first opportunity which occurs, of making another opening in a convenient situation; and it will often happen that several such openings will be required before the cure is completed." The employment of exploring needles (says the reviewer) has certainly found its chief champion in the writer of the volume before us, and against so great an authority it is difficult to contend. The practice is, however, in our view, a questionable because a dangerous one; and, as we have many times heard it said by perhaps as great a surgeon as Sir Benjamin, need rarely or never be resorted to by a man of tact and experience. We do not of course mean to say, that there is not often extreme difficulty in diagnosing the nature of a tumour, or the contents of a cyst; but we do mean to say, that by unnecessary exploratory punctures, many a malignant growth has been excited to inflame and increase, when it was in a quiescent state.—*Brit. and For. Med. Chir. Rev.*

Mercury in Syphilis.—The mode of employing mercury in the treatment of syphilitic sores by Mr. B. Cooper, and which was taught him by his uncle, Sir Astley Cooper, is as follows. He applies the common black-wash upon common linen rather than lint, as he supposes the latter to produce very frequently great irritation. He orders two kinds of mercurial pills: one kind consisting of five grains of blue-pill and ¼ grain of opium each, to be taken at bed-time; and five grains of blue-pill only, to be taken in the morning. If the bowels are constipated, the "morning pills" only are to be taken both night and morning; but if they become relaxed, then the "night pills" are to be taken. Mr. Cooper thinks that although iodine or the iodide of potassium may suspend the symptoms for a time, they do not eradicate the poison entirely from the system, or secure the patient from future attacks. A further continuance even of this remedy seems in many instances to increase the violence of the symptoms. In sloughing phagedæna mercury must be withheld; the remedies are the local application of nitric acid and the internal administration of opium.

CASE OF INTESTINAL OBSTRUCTION FROM WORMS.

By Dr. Dunn of Frankfort, Hampshire Co., Virginia, U.S.

On June 19, 1851, I was called in haste to visit an interesting little girl, aged 6, delicate make and constitution, black hair and eyes, nervous temperament, cheerful and sprightly. She has had several attacks of convulsions heretofore, from improper diet and worms irritating the bowels. At these times I have always attended her. Although seriously menaced, she has always partially recovered from these attacks. She was taken some two weeks since with diarrhœa, which is epidemic here, and has been for some weeks. Her parents undertook to treat her with two or three others of their children. She had taken ol. ric. and tinct. opii several times, three doses of calomel, decoct. rad. spigelia, &c., and had passed several worms. I was called in on account of her bowels not moving under the influence of the above medicine, and that she had called their attention to a considerable tumour in the abdomen, tender to the touch, from which colicky pains diffused themselves over the abdomen. Her stomach had become irritable and rejected the medicines, &c., and her bowels had not been moved for thirty hours. On examination, her pulse was quick; not much tension; tongue covered with yellow mucus, white underneath, narrow and pointed, rather red at the edges, not very dry; skin rather dry, and warm abdomen; general intumescence moderate. The tumour above alluded to was situated in the right lumbar and hypochondriac regions, extending from about the head of the colon up under the ribs above in a gentle curve. Its base or large end was below, and it grew smaller as it passed upwards. Its length was six or seven inches, and as thick as my wrist; towards the lower end its surface was irregular and knotty. Its touch gave the idea of something pretty solid, yet elastic, quite tender, though not discoloured from inflammation on the surface. It seemed to be attached to some internal organ; but upon insinuating my fingers under its edge, I found it could be moved with facility. On mature deliberation, taking the patient's former habits into account, my diagnosis was obstipatio, with threatened ileus, from a mass of convoluted worms mechanically blocking up the alimentary canal at or near the ileo-cœcal valve and caput coli, &c. ℞ Hyd. chlorid. gr. iv. every four hours; infus. senna et man. in aq. menth. virid.; decoct. rad. spigel. As much of these articles as the stomach would bear; injections of saltwater between every dose of calomel; sinapism of mustard to the epigastrium; cloths wrung out of hot spirits to the tumour and lower abdomen.

At nine p.m., visited her again; bowels had not moved; she had kept all the medicine given; injection retained without anything else; she had been on the close vessel several times; a little more tension about the abdomen; tumour about as it was. Ordered the same course kept up through the night.

20th, six a.m., visited her again; things pretty much as they were last night; bowels had not moved, although she had taken the medicine freely, retained it, and had several injections; she had been up to the vessel several times; nothing passed save what had been thrown up the bowels; abdomen more tumid; more fever; tongue more contracted and dry; red on the edges and point; not much resistance in pulse, though irritable and quick. ℞ Hyd. chlorid. gr. iv. continued as above; decoct. rad. spigel. continued also; ol. ric. a large spoonful; ol. terebinth. rect. teaspoonful. These articles to be given between each calomel powder; fomentations to the tumour and abdomen continued.

Twelve o'clock, visited her again; found her as I left her in the morning; she had retained all the medicine; been up often to the vessel, but nothing passed except what had been thrown up; tension of the abdomen increased a little; tenderness of the tumour also increased a little; more general uneasiness. I concluded to give her the injection myself, and placed her on her mother's lap, so as to relax the abdomen, with a view to distend the bowels as much as possible with safety. I introduced the point of the instrument, but had scarcely moved the piston, when by an involuntary effort, the bowels moved slightly, upon which I desisted. I found that matter had passed from above the stricture in a small quantity. In a few minutes they moved again more freely, with several lumbrici dead and stiff; in an hour or so they moved the third time still more freely, with a knot of convoluted lumbrici, 29 in number, upon which the urgent symptoms abated considerably. The tumour could still be felt distinctly, although the tension and tenderness had much abated. Ordered the course continued through the evening.

Six p.m., bowels had moved several times, worms passing in every stool. She passed about 65 altogether this afternoon. Ordered the medicine at more distant intervals, six hours.

21st, six a.m., much improved; bowels moved two or three times through the night; worms still passing in every stool. I now substituted the infus. sen. et man. for the ol. ric. and turpentine; the rad. spigel. continued; all general intumescence of the abdomen had now disappeared; the tumour was still to be felt, but very much lessened. Sensibility not much on pressure. Under this course she improved, passing off worms for several days, until she passed upwards of 100. At this time, 27th, she is playing about with the other children as lively and sprightly as ever.

We take the liberty of publishing the subjoined extract from a private letter from Dr. Dunn. We are glad to say that we have received many letters from different parts of the state, showing that the work of organization is going on, and that societies are being formed :—

Dear Sir,—I had the above case under treatment, when a medical friend handed me your May number of the *Stethoscope*. I was struck with the analogy of it to the one published by Dr. Joynes of Accomack county, in the above number. The symptoms much the same; the locality of the obstruction different in his case; the obstruction no doubt was in the ileum-intestinum mem. in the lower part of the same bowel, where it ends in the colon and also in the ascending colon; about the ileo-cœcal valve seemed to be the most solid and tender part of the tumour. As this case has the same bearing as his on those pathological subjects brought up in his observations, you can publish it if you think proper to do so. Verminous diseases are common in this country. Diarrhœa is epidemic here, mild in character, and easily controlled if prudently managed, but assuming a dysenteric shape if trifled with.

I am fully impressed with the importance of state organization, and the other subject touched upon in connexion therewith, in the above number, and hope you will continue to press these subjects on the profession. I have been trying to organize a medical society in this and Hardy counties for some time, and as there is more stir on the subject at this time than usual, I think it will soon be effected.—*Stethoscope, Virginia, U. S.*

Iodine rendered Soluble in Water.—After many attempts to render soluble in water, without the use of iodide of potassium, the small quantities of iodine, in the form of tincture, which are prescribed in draughts, M. Debaugne was led to discover that the addition of an ounce of syrup of orange-peel to a four or six ounce mixture, renders five or six grains of iodine perfectly soluble in this quantity of fluid. In investigating as to which of the constituents of the orange-peel had this effect on the iodine, he came to the conclusion that it was due to the tannin. In order to determine the truth of this supposition, M. Debaugne made several experiments, and had recourse to the addition of a few grains of tannin to water, containing ten, twelve, or even fifteen grains of iodine, precipitated from the tincture when added to it. After a few moments' agitation, the solution became complete, and thus proved that it was by the tannin that the iodine had been rendered soluble. Being unable to explain why this vegetable acid should thus favour the solution of iodine in watery vehicles—an effect not produced even by the most powerful mineral acids—he contents himself with establishing this fact, which appears hitherto to have been unknown. He recommends to practitioners to have recourse to syrup of orange-peel in draughts containing tincture of iodine, and the addition of a few grains of tannic acid in the preparation of iodine injections.—*Jour. de Phar.* and *Ed. Jr.*

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, OCTOBER 1, 1851.

OPERATION OF THE NEW DISPENSARY ACT.

ALTHOUGH this measure has not yet come into operation, not even the appointments under its provisions, up to the moment we write, having been made, the method of carrying it into effect has already been suggested in reference to one important point. In the provision for forming Dispensary Districts by the union of electoral divisions, it does not appear that any power has been reserved for boards of guardians of unions adjoining each other to coöperate for the accomplishment of this object. In other words, it does not appear that electoral divisions on the bounds of one union, however conveniently circumstanced for the formation of a Dispensary District with corresponding divisions in the next, can be united. The following proceedings raise the question, and our opinion, on a cursory view of the act, leads us to conclude that the object, if found desirable, can be effected. In carrying this act into operation, a very rigorous adherence to its words may cause much difficulty, and cavilling at the readings of it which contemplate its real intention, may lead to endless wrangling. The object of all should be to promote its peaceful and beneficial operation by a candid adoption of its obvious intention, rather than any torturing of its details by ingenious legal refinements. We advise our brethren to make up their minds to place as much confidence as possible in the construction put upon it by those entrusted with its execution, and however adverse such may be to their views, to lean to the belief that it is the correct one. Above all things, we warn them against what are called "law opinions," which are always to be had to suit the wants of clients. For ourselves, we wish it to be understood, while yet the executive of this department is unknown, that we are determined to contribute by every means in our power to the just and efficient application of the measure:—

At a meeting of the subscribers to the Annadown dispensary, held on the 15th inst., for the purpose of recommending to the guardians of the Galway and Tuam unions and the commissioners, the district to be appointed for the attendance of the medical gentlemen under the new Medical Charities' Bill, the following resolutions were proposed and unanimously agreed to:—

"That the several electoral divisions hereinafter named, forming part of the Galway union, and the following electoral divisions hereinafter named, forming part of the Tuam union, should form a dispensary district, and that the guardians of the Galway and Tuam unions shall be requested to approve of such arrangement—viz., *Galway Union:* Annadown, Liscananaun, Lackaghbeg, Claregalway. *Tuam Union:* Annadown, Ballinduff, Killower, Kilcooney."

"That from the very efficient manner in which Dr. Keaven, the present dispensary physician, has discharged his duties, he is most strongly recommended by this meeting to the commissioners to be appointed to said dispensary district."

In reference to this the *Galway Vindicator* contains the following editorial comment:—

In our advertising columns will be found a notice of a meeting held at Annadown for the purpose of mapping out a dispensary district under the new Medical Charities' Bill. At the meeting, which was largely and most respectably attended, an unanimous desire was expressed for the appointment of Dr. Keaven as medical officer to the district, and a resolution to that effect was adopted. The subscribers could not have made a better selection, as Dr. Keaven is a gentleman of courteous and bland manners, of affable demeanour, skilled in his profession, and most attentive in the discharge of all his duties. We believe this is the first meeting of the sort which has been held under the new bill, and we trust the commissioners will give the country a proof of their common sense in allowing public opinion, when so unanimously and uninterestedly expressed, to have its proper influence on their counsels, and that they will accede to the wishes of the people of this district by appointing Dr. Keaven their medical officer.

HOMŒOPATHY *v.* ALLOPATHY.

WE copy the following from the columns of a London contemporary, although we do not exactly coincide in the views of the writer. Homœopathy and the absurdities of infinitesimal doses, are proper subjects for reprobation, but denunciations of practitioners who rely on minute doses of very powerful remedies are not so much to be encouraged. We can very well understand why an extremely cautious administration of medicine is not agreeable to the apothecaries of England (the so-called General Practitioners), but if they suppose that educated and conscientious physicians and surgeons are to be bullied into a participation in their system they are mistaken. It is obvious that something of a panic prevails in the drug market; there is what COBBET used to call "a rustling under the straw," which indicates apprehensions of an enemy; and to say the truth, we do not regret it. The advocates of free trade in matters medical have an account to settle with their heretofore rampant opponents, which we hope is on the eve of settlement, and we shall have great pleasure in assisting to strike the balance:—

HOMŒOPATHIC QUACKERY.

In pursuance of the resolution we announced, to publish everything relating to this subject which came distinctly before us, we consider it to be right to bring under the notice of Sir James Clark and Dr. Locock the following extracts taken from one of the quack publications:—

"*Homœopathy in High Places.—To the Editor of the* ———.

SIR,—Knowing that you gladly receive any information indicative of progress in a right direction, I venture to send you copies of two prescriptions that accidentally came into my hands at a watering-place in one of the eastern counties, where a malignant scarlet fever raged with fearfully fatal violence last year.

For Scarlet Fever

Sir James Clark's Prescription.—'Extract of belladonna, five grains; cinnamon-water, two ounces. Number of drops according to patient's age, before breakfast, not exceeding twenty, in about two tablespoonfuls of water.'

Dr. Locock's Prescription (for a boy ten or eleven years old, who was exposed to the infection).—'Extract of belladonna, three grains; cinnamon-water, one ounce and a half; of the solution twenty drops to be taken three times a day.'

Do the allopathic physicians, who prescribe homœopathically, give honour to whom honour is due?—I am, Mr. Editor, A LOVER OF FAIR PLAY."

The following remarks are from the editor of the paper:—

"Most of our readers are fully aware of the fact that the practitioners of the allopathic school ever and anon resort to remedies given on the homœopathic principle—aconite, arnica, and belladonna have been again and again given in this way by many allopathists. The two eminent physicians, mentioned by our correspondent, have distinguished themselves by their gentlemanly forbearance and by their courteous demeanour towards their homœopathic brethren. Neither of them has ever made any difficulty of meeting in consultation, at the request of the patient, any homœopathic practitioner, not for the treatment, but for an opinion of disease. Other eminent men of the 'Faculty' have no less stood aloof from the intolerant bigotry and insolent exclusiveism of a certain class of allopathists."

In all probability Sir James Clark and Dr. Locock will not allow statements so injurious to their reputation to remain unnoticed and unrefuted.—*Lancet.*

THE EDINBURGH QUACKERIES.

Be the cause what it may, it is obvious enough that our friends in "Auld Reekie" have got into a mess. There has been evidently a slight paroxysm of the national malady which, from time to time, disturbs the equilibrium of social ingredients in the "land o' cakes!" The ghosts of Mesmer, Hahnemann, Prince Hohenlohe, and Valentine Greatreakes, have probably been taking advantage of an excursion train to enjoy a tour to the North; and the result has been the ferment to which the following refers. We do not, however, adopt all the bitter things contained in this document. Although we have little respect for the disciples of great quacks, we are not such bigots as to deny some toleration to them. In medicine we must make allowances for the infirmities of human nature as we do with reference to religious aberrations; besides these vagaries provoke discussion on subjects which might otherwise remain untouched. The absurdity of infinitesimal doses suggests an inquiry into the absurdity of heroic doses, and so the cause of medical science is served. Moreover, we like to see men doing, though they may be doing wrong; for of all things in the world we hate that fat contented ignorance which prevails somewhere we care not to mention:—

The members of the Town Council of Edinburgh are the patrons of the University. Most of them are known to be conscientious men, and keenly alive to all that can affect the honour and the usefulness of the institution over which they preside. It appears extraordinary that they should have remained so long unacquainted with the leprosy which has infected some of the professors; or that they should not have summarily driven these persons from the chairs they were polluting, when the fact was discovered. The blame does not, however, rest so much upon the patrons as upon those medical professors of the university who, after years of silent connivance at the abuses which they know to exist, have now stepped out to denounce them, after they had been denounced so loudly in the *Lancet*. The Town Council could not have thought that homœopathy and mesmerism were such dangerous errors, and so much to be condemned, when they publicly saw Dr. Simpson, the President of the College of Physicians and Professor of Midwifery, meeting the homœopathic professor in consultation, and throwing open his house for mesmeric *soirées*. The Town Council must have felt bewildered, and greatly at a loss how to proceed, when they saw Professors Simpson and Syme privately countenancing quackery, and then publicly denouncing it. But for this inconsistent conduct, on the part of the President of the College of Physicians more especially, it is impossible to believe that the rampant quackery in the University and among the population of Edinburgh could ever have reached the present disgraceful position. But it is not homœopathy and mesmerism only which Dr. Simpson has fostered, it is to him that we chiefly owe the infinitely more dangerous and disgusting quackery in midwifery, which rages like a pestilence in London, and in every town and village throughout the empire, and in some of our most distant colonies. On the present occasion, it may be sufficient to enumerate the proceedings to which I allude. To Dr. Simpson we owe the invention of the dangerous weapon called the uterine sound or poker; pessaries which have justly been designated infernal and impaling uterine machines, to cure retroversions which never existed; instruments for pumping the uterus, to excite menstruation; and the proposal to rub its inner surface with lunar caustic, for the same purpose. To him we owe the hysterotome, for slitting open the os uteri, to cure sterility; and to his efforts, more than any other individual, we are indebted for the profligate use of the speculum which has prevailed, and the practice of destroying the os and cervix uteri with caustic potash. To Dr. Simpson we owe the attempt to revive the brutal practice of turning in cases of distortion of the pelvis; of attempting to substitute the Cæsarian operation for the induction of premature labour, as witnessed by the whole world in the famous Cupar case. To him we owe the attempt to subvert the established practice in placental presentation, by extraordinary statistic tables; and lastly, we owe to the genius of the Professor of Midwifery in the University of Edinburgh, the baby-sucker! Are these specimens of what the *Edinburgh Monthly Journal* for this month calls "the simple treatment taught and practised in Edinburgh, and which, if adopted in London, would reduce many practitioners from comfort to starvation"? We may well excuse the members of the Town Council if they are not so dexterous in *Harlequinade* as the university professor.—*Letter of Dr. Irons in Lancet.*

REPUDIATION OF "ANIMAL MAGNETISM" BY PROFESSOR SIMPSON OF EDINBURGH.

It is but fair to afford Professor Simpson an opportunity of disavowing a perception of this phantasm, or any belief in the potency of the spright who personifies the hallucination. It is too serious an imputation as regards a man's mental sanity to be endured:—

To the Editor of the Lancet.

Sir,—During the last few months I have been more than once directly or indirectly alluded to in your leading and other articles in tones of reprehension, and have been broadly accused of committing professional faults which I never committed, and of holding opinions which I never held. Sometimes your editorial accusations have been in the form of extracts from the writings of others; sometimes they have consisted of observations offered by yourself.* I have not of late answered any of these accusations, partly because the task of doing so is always a disagreeable task, and partly because I fear and feel that I am getting too old and callous to care about such things. In your journal of Saturday last there is a renewed attack upon me in an editorial article, in which I am held up by you as a believer in animal magnetism; and at the urgent request of an esteemed London medical friend, upon whose judgment I place very great reliance, I at last unwillingly take up my pen to say that on this, as on various other former occasions, your accusation is erroneous. I do not believe, and never did believe, in animal magnetism. During the last ten or fifteen years I have repeatedly seen experiments made upon the subject, and have repeatedly made them myself. In the course of them I have witnessed very interesting physiological and psychological results, such as the production of deep sleep, fixture and rigidity of muscles, lesions and perversions of sense, &c.; but I have no belief whatever that these effects are the effects of any power, force, agency, or entity, such as is understood by the term animal magnetism, passing from the so-called mesmerizer to the so-called mesmerized. On the contrary, these experiments have firmly convinced me, as they have convinced others who have seen them, that these and other phenomena of the like kind are merely effects produced by the mind of the mesmerized upon his or her own economy; that they are only self-mental acts, if I may so speak, and that they are as independent of any mesmeric influence as the phenomena of common sleep, or common dreaming, or common hysteria, are. If you or any of your readers have, perchance, any desire to know more explicitly my opinions on the subject, you will find them stated at greater length in the May num-

* Thus, for example, two or three months ago you stated, in one of your editorial articles, that an Edinburgh physician (and the allusion was intended to apply to me) had come up from Edinburgh as far as London, to hold a consultation with a homœopathic physician at Brighton, but that I found professional feeling so "hot" upon the subject that I wisely returned. So far was this from being the fact, that I wrote from Edinburgh immediately on receiving the letter from Brighton, and stated that I was engaged to visit professionally, as soon as I could possibly leave Edinburgh, two chronic cases, the one in London and the other in Paris; that I would thus pass and repass near to Brighton, but that I could not meet the practitioner, as he was known to me to be a homœopathist. Let me add, that I believe that professional opinion is "hotter," and in a healthier state upon this subject in Edinburgh than in London. When in London on the occasion referred to, I was told by one of your first surgeons, that he was attending the foot of a noble duke, whilst a celebrated homœopathist was attending to his grace's stomach and constitution. Whatever laxity may have existed on the question, here or elsewhere, in past times, there exists none now in Edinburgh, since the colleges have taken up the subject, and pronounced upon it.

ber of the *Monthly Journal of Medical Science*, in a discussion on the subject of Electro-Biology, before the Edinburgh Medico-Chirurgical Society. In that report it is, *inter alia*, mentioned that (to quote the words of the report) "Dr. Simpson stated that he totally disbelieved in any of the so-called higher phenomena of animal magnetism—as lucidity, transference of the senses, clairvoyance, &c. If a person could see with the tips of his fingers or the pit of his stomach, as was averred, it would be an enormous fact, and would require an enormous amount of proof to substantiate it as a fact. But the evidence adduced was generally of a very imperfect kind, and melted down before accurate inquiry. He had such a conviction of this, that he offered to place in the president's hand £100, which he would give to Dr. Macdonald for the scheme for which he (Dr. M.) was lecturing, if Dr. Macdonald could bring any clairvoyant who could read a line of Shakspeare, or two or three words out of the dictionary which Dr. Simpson would shut up in a box. If there was any truth in clairvoyance, why should not a clairvoyant be able to gain for Dr. Macdonald this sum of money?" Now, to show you the sincerity of my belief, let me put this same proposition in another shape:—I will, if you will allow me, place five such boxes or packets (each of them containing a line of Shakspeare) in your hands, and in the hands of a small committee of medical men, whom you and I shall conjointly agree upon, and who, with you, shall be judges, and make all the necessary arrangements; and I now offer, through you, £500, for the reading of these included five lines by any clairvoyant. Further, as my pen is in my hand, let my name at once, on my part, your fellow-citizens, Dr. Sharpey, Dr. Locock, Dr. Williams, Dr. Todd, and Dr. Carpenter, or any two or more of them, to adjudge the matter with an equal number named by you. Perhaps you will agree with me in thinking, that in settling a question of this nature, such a test and trial is better than any other five hundred arguments.—Yours, &c. J. Y. Simpson.

Edinburgh, Sept. 15, 1851.

P.S.—Is it necessary, after the preceding statement to add, that you are again in error in your reference to the miscalled "mesmeric soirées." The object of the experiments comprised in this designation is to show, that many striking effects can be produced by the influence of the will of an individual, acting on another, independently of any magnetic, mesmeric, or other supposed agency. These experiments are, therefore, directly and entirely opposed to the so-called doctrines of "mesmerism."

THE BRANDING OF DESERTERS BY ARMY SURGEONS.

This arbitrary and illegal exercise of drum-head authority continues to elicit universal reprobation, of which the following from a London contemporary is an example. If persevered in it must be resisted by every lawful means as a gross outrage on our profession and a very obvious usurpation of power by parties prone to such methods of preserving order amongst their subordinates. If necessary the subject will be brought under observation in parliament, and then perhaps the principle which dictates such ordinances may be subjected to a discussion not very convenient or opportune. The subject of military punishments had better receive consideration elsewhere: it is not a very agreeable one for popular discussion:—

If the authorities at the Horse Guards really intend to carry out their monstrous order for branding deserters, by which army surgeons are to be converted into executioners, we hope they have bargained for the steady and unremitting opposition of the entire profession. The order is not only monstrous, but absurd. It is not a year since the Military Order of the Bath was conferred upon the medical department of the army. Future Knight-Commanders will have, according to this order, to begin their career as the allies of the hangman. A new subject must be added to military surgery; students must be taught, not only how to heal wounds, but how to make them, according to the art and mystery of branding—a disgusting proceeding, hitherto carried out by the drummers. We cannot believe that this order will be seriously attempted to be carried into effect. If the attempt be made, we are sure that the surgeons of the army will refuse to be degraded by such an occupation. In this refusal we are confident they will meet the hearty sympathy and support of their civil brethren. It seems incredible that such an order should have been promulgated at all. The practice of branding at all is most barbarous and inhuman, unworthy of the age and country in which we live. Like the odious system of whipping, it should be erased from our criminal code. It is loathsome to contemplate the fact that a clause of an act of parliament exists according to which the flesh of living men is seared by red-hot irons. That act, however, never contemplated that the professors of the art of healing should carry its odious provisions into execution. General Brown, and the parties who have concocted this order, must entertain a very imperfect notion of the sentiments of civil or military surgeons, if they imagine that any force can be found to make them prostitute their noble profession to such a disgusting purpose as that of mangling the bodies of deserters.—*Lancet.*

THE MEDICAL DIRECTORY FOR IRELAND.

We earnestly entreat our brethren throughout the provinces to use their best endeavours to promote the accomplishment of the object contemplated by this publication. They may rely upon it that sooner or later it will prove of value to every individual whose name appears in it. It will become an authentic record of a man's professional *status*, and the only unequivocal evidence of his claims to public confidence by virtue of his qualification; so much so, that the omission of his name from its columns may seriously injure his character. The Almanacks and Directories afford no adequate substitute for such a list, accepting, as the publishers of them do, imperfect evidence of the claims of individuals to the titles they assume; and therefore is it incumbent on every regular member of the medical profession to enable the public to become satisfied of his identity. We feel called on to say so much because we understand that many have failed to respond to the invitation sent them by the publishers to transmit their names for enrolment, and that there is great danger of the list appearing without the names of several persons, to their great detriment. Should this take place, they will have themselves only to blame, and therefore do we thus warn them. It is only fair to the parties who have undertaken this useful work to give them substantial support by ordering a copy of the publication to be supplied in return for the benefit afforded by the insertion of name and titles. Let it not be supposed that we have any, the slightest, interest whatever in the success of this undertaking; we advocate its cause, because by doing so we are convinced that we promote the welfare of our brethren throughout the country.

MILITARY SURGERY.

We are informed that in the ensuing medical session it is the intention of the authorities connected with one of the principal London schools to open a course of lectures specially devoted to Military Surgery, so that this metropolis will in future possess the advantages that Edinburgh and Dublin have enjoyed for some time past. Two gentlemen, we are given to understand, who are in every way qualified for this department, from their long experience and residence abroad, are in treaty with the several public departments, and hope, through the aid of the East India Board of Directors, to be enabled to establish this course of lectures on a permanent basis. It is not their intention to enter on any of the subjects at present available to students at the different colleges and schools, but barely to confine themselves to those subjects which more immediately appertain to the duties of a medical officer on his first joining his regiment, ship, or depôt, on home or foreign stations. These duties very often become at once onerous and anxious, more especially on a foreign station, where he has not only to contend with climate, but with an entirely new class of diseases, and with the majority of which he is in all probability perfectly unacquainted. How few young surgeons hear or see much of what they have

to meet with daily after their arrival in a tropical climate! Our hospitals rarely afford an opportunity of studying any of the diseases incidental to Orientals, or Aboriginal tribes, or even to Europeans long resident in tropical countries. The subject of Climate itself is one requiring much careful consideration in relation to their own health after their arrival, and still more to the large bodies of men under their medical charge then and subsequently. It is not yet decided whether this course of lectures may not better be made a summer or a winter course. On two grounds it appears desirable to adopt the former; first, because, on the matter being put to some of the leading men in the profession, it was objected to its being a winter course—for the reason, namely, that the students are already overworked, and have very little time at their command for any more lectures: and secondly, that the great body of surgeons from the East India Company going to India, leave this country in the autumn; so that they could thus attend the summer course at their leisure, and when not over-pressed from their other studies; and then, again (and this is an important consideration), they would go out fully stocked from these lectures, and be the better prepared to enter upon their duties, and carry their recent theories and deductions into practice at once. It is, then, for the present entirely a matter for the public boards to arrange this point as to a winter or summer course. It should be borne in mind that this course is not intended for all students, but for those who have completed or nearly finished their studies, or who have already passed their examinations; so that it is of little importance, we conceive, whether it be a winter or spring course, so far as advanced students or surgeons are concerned.—*Med. Gaz.*

THE REVERSED AND DOUBLE-ACTIONED PATENT TRUSS.

Invented by FRANCIS L'ESTRANGE, Esq., F.R.C.S.I.

WILLIAM DUFF, of 37, Molesworth-street, Dublin, calls the attention of the medical profession and the public to this Truss. He can state with confidence it is the only instrument constructed on scientific principles, having for its object the Radical Cure of Rupture. It acts not merely as a palliative, but will produce a radical cure, as is attested by numerous certificates.

W. D. is the only Manufacturer of the Instrument. The trade and public institutions will be liberally dealt with.

ROYAL COLLEGE OF SURGEONS.

SCHOOL OF SURGERY.

THE Session 1851–2 will not commence until the 27th of October. Gentlemen, however, residing in Dublin can commence their Dissections immediately on entering their names for the ensuing Winter Course of Practical Anatomy.

UNIVERSITY OF LONDON.

NOTICE is hereby given, that the Second Examination for the Degree of BACHELOR of MEDICINE, for the present year, will commence on Monday, the 3rd of November; and that for the Degree of DOCTOR of MEDICINE on Monday, the 24th of November.

The Certificates required must be transmitted to the Registrar fourteen days before the commencement of the Examination to which they refer.

By order of the Senate,
R. W. ROTHMAN, Registrar.

Somerset House, Sept. 22, 1851.

QUEEN'S COLLEGE, CORK.

FACULTY OF MEDICINE.

SESSION 1851–52.

THE Session will be opened on Wednesday, November the 5th, 1851, at One o'clock.

The Practical Anatomy Department will be opened on the 1st of October.

On Tuesday, the 21st of October, 1851, the Matriculation Examination will be held for the admission of Students.

Six Scholarships, of the value of £20 each, will be awarded to Matriculated Students in Medicine, and in all future years there will be two additional Scholarships of £40 each.

PRIZES.—Prizes will be awarded in each class, to such of the Matriculated Students as exhibit the greatest proficiency.

The Library and the various Museums are open, under certain regulations, to all Students in Medicine.

For more detailed information, application to be made to the Registrar.

D. C. O'CONNOR, Dean of Faculty.
By order of the President,
FRANCIS ALBANI, Registrar.

August 29, 1851.

DISPENSING OF MEDICINE.

G. OLDHAM AND CO.,

PHARMACEUTICAL CHEMISTS AND APOTHECARIES,
From BEWLEY and EVANS',
No. 107, GRAFTON-STREET, DUBLIN,
(Corner of Suffolk-street,)

BEG to return their grateful acknowledgments to the Medical Profession for the support they have hitherto received, and which they will regard as a fresh motive for exertion. Abstaining altogether from visiting as Apothecaries, except for the application of Leeches, Cupping, and such operations as are performed under medical advice, they will continue to devote themselves exclusively to the duties devolving on the pure Pharmacien.

Having had much experience in Practical Pharmacy, and being resolved to spare neither trouble nor expense in order to have every article of superior quality, they hope by attention, "carefulness," punctuality, and moderation of charges, to commend themselves to the approbation of those who may entrust them with their commands.

☞ *G. O. and Co. invite attention to their present stock of Surgical Instruments, all of which are manufactured on the most modern and improved principles.*

LOUTH COUNTY INFIRMARY.

NOTICE is hereby given, that the Governors of the Louth Infirmary will, on Friday, the 3rd of October next, receive applications, and proceed to appoint two Nurses for the establishment. (A Male Attendant for the Male Patients will be preferred.)

Candidates will be required to send in their recommendations to me on or before Thursday, the 2nd of October next, and to attend personally at the Infirmary at one o'clock on the day of Election.

Signed by order,
ALEXANDER SHEKLETON, Secretary.

W. Boylan, Registrar.

CITY OF DUBLIN HOSPITAL.

The Course of Practical, Medical, and Surgical Instruction in this Hospital will commence on Monday, the 27th of October. The Clinical Lectures will be delivered on three days in each week, during the Session, by Dr. Jacob, Dr. Benson, Mr. Hargrave, Mr. Williams, Dr. Geoghegan, and Mr. Tufnell; and on Diseases peculiar to Women and Children, by Dr. Beatty.

Dr. Jacob's Clinical Lectures on DISEASES of the EYE, illustrated by the Cases in the Hospital, are open to the Pupils in attendance.

Sir Henry Marsh, Sir Philip Crampton, Dr. Apjohn, Mr. Porter, and Mr. Cusack, give their assistance in cases requiring consultation.

The certificates of attendance are received as qualification by all the Colleges, Halls, and Boards.

DISEASES OF THE EYE.

DR. JACOB will deliver a full Course of Lectures on the Anatomy, Physiology, and Optical Mechanism of the Eye, during the ensuing Session, in the College of Surgeons, and also a separate Course on its Pathology and Diseases, with the Operations required in their Treatment, in the City of Dublin Hospital.

Printed by Thomas Dees, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, Arthur Jacob, M.D., 23, Ely-place, in the City of Dublin. London: John Churchill, 46, Princes-street, Soho.

Case of Encephaloid Growth, developed in the Cavity of the Chest, compressing the Superior Cava, and causing Anasarca of the upper part of the Body—Farre's Tubercle of the Liver.

Thomas Whelan, aged 52, admitted into St. Vincent's Hospital, under Dr. Bellingham, July 20, 1850, on the recommendation of Dr. Leeson. He was always a healthy man until about nine weeks ago, when, after exposure to cold, he was attacked with "pains in his bones." A little more than five weeks ago he noticed a swelling in the region of the liver, which subsequently increased in size, and his breathing became much affected; and while suffering from the pains, he says a swelling, which is now visible, formed suddenly, during his sleep, over the sternal extremity of the left clavicle. About five weeks ago he noticed a tumour above the right clavicle, and he has suffered since from difficulty in swallowing. He has laboured under dyspnœa in a severe form for the last eight weeks, but latterly it has much increased; he cannot lie upon either side; lies constantly upon the back, and says he has been obliged to do so for the last eight weeks.

On examination, a tumour is felt in the region of the left lobe of the liver, which is hard to the feel and is painful on pressure. Another tumour, having a harder feel, is seen above the right clavicle, flattened upon the surface, and of large size. In the situation of the sternal extremity of the left clavicle, a rounded, softer tumour is felt, and this extremity of the clavicle is protruded forwards. The face, neck, and left arm are swollen, particularly the latter, which is œdematous; the former are congested, with enlarged veins, and when he sits up the face assumes a more dusky hue. Enlarged and tortuous veins are seen along the chest and abdomen, the mammary inosculating with the epigastric. He suffers greatly from dyspnœa; the respiration is loud and noisy, and on placing the stethoscope upon any part of the chest, above or below, or even beyond the region of the chest, a loud sibilous and sonorous râle is audible with both inspiration and expiration, giving the sensation as if the large bronchial tubes were compressed by some foreign substance; the pulse in the right wrist is small and feeble, in the left it cannot be felt; he says he met with an injury some years before in that arm, when the artery of that side was cut across. He lies constantly on the back, with the head raised; he cannot lie upon either side, or sit up, as his breathing becomes then more difficult, and his face becomes purple. He complains also of numbness along the nates and back of right thigh, reaching to the calf of the leg, which he has had for a month. He suffers also from difficulty of swallowing solids; can swallow liquids readily.

The patient lived only a few days after his admission, and died July 23rd. On examination, both arms were œdematous, and the face and neck were swollen, while the lower extremities were emaciated; the swelling in the region of the liver was found to be formed by a large white, flattened, cancerous tubercle seated in its tissue, which had softened in the centre; two smaller and similar tumours were also found in other parts of the liver. The swelling above the right clavicle was of the same nature as the tubercle in the liver; on tracing it, it was found to extend under the clavicle into the thorax, where it formed an irregular nodulated mass of encephaloid growth, being connected in front closely to the posterior part of the upper bone of the sternum; below, with the upper portion of the pericardium, and extending backwards to the spine, to which it was adherent above. The superior cava was surrounded and compressed by the morbid growth, which also pressed upon the trachea, œsophagus, and the divisions of the trachea. The right pleura contained a large amount of serum, recently effused, which had compressed the lung. Another tumour, of a similar nature, on the left side, surrounded the descending aorta, and had contracted adhesions with the diaphragm and with the lower lobe of the left lung. A smaller and similar tumour was connected with the pancreas.

On examination of a portion with the microscope by Dr. Carte, numerous cancer cells were seen in it.

Case of sudden Development of Encephaloid Disease in several distinct situations.

Charles Clarke, a carpenter, ætat. 54, admitted into St. Vincent's Hospital, under Dr. Bellingham, February 11th, 1851. He states that he always enjoyed good health until his present illness; had not had occasion for any medical treatment for forty years previously. Five weeks ago he observed a swelling in the left groin, which commenced, he says, as a small kernel, and when first noticed was only the size of a pigeon's egg; it has gradually increased since. About the same time he observed a swelling in the left axilla, which, by means of poulticing, &c., he says, disappeared. Soon afterwards a swelling in the right groin was observed, similar to that on the other side. Three weeks ago another swelling appeared in the right axilla, which has rapidly enlarged, and from which he has suffered very severe pain, extending to the elbow. A tumour is also observed on the right side of the face; and several smaller ones on the neck and under the chin.

On examination, the patient has an anxious expression of countenance. He says he has suffered very great pain during the last three weeks, referred to the right shoulder and arm, extending to the elbow. A very large tumour occupies the right axilla, which extends from the clavicle to the nipple, and protrudes the right scapula backwards; its surface is smooth, it is hard to the touch, and the surface is marked by veins. The arm and hand on this side are swollen and œdematous. In the left axilla several hard, rounded, and apparently enlarged glands are to be felt. In the neck and under the chin, on each side, are several others, like marbles, under the skin; and on the right side of the face, in front of the ear, a larger one, about the size of a duck's egg, but of a somewhat different shape, is seen. In each groin very large tumours are seen, which have the same feel and appearance as the tumour in the axilla; that on the right side has a purple livid colour. Nothing abnormal is observed in the testis or penis.

February 27th. The tumour on the right side of the chest has increased in size; its surface towards the axilla presents a bluish tinge, and it rises now above the right clavicle. The tumour on the side of the face has increased very rapidly, and is now the size of an orange, and its surface has a deeply livid hue. He suffers considerable pain in it. The right arm is now œdematous, and to move it he is obliged to raise it with the other hand. He does not suffer pain from the inguinal tumours. He is more emaciated.

28th. The patient wished to return home, and left the hospital this day. He was seen a few days afterwards; the skin upon the tumour on the side of the face had given way, and a bloody serum exuded from it.

Case of Encephaloid Disease of the Knee-joint.

Henry White, ætat. 59, in the grocery business, admitted into St. Vincent's Hospital, under Dr. Bellingham, April 16, 1850, labouring under disease of the left knee-joint. He states that in September, 1848, he fell in the street in consequence of striking his foot against a stone, his left knee twisted or turned under him, and he came to the ground upon the right shoulder. He suffered very severe pain at the time, and was confined to his bed for nearly two months in consequence. The joint remained stiff afterwards, but still he was able to go about. At Christmas last he received a blow a little above the knee, and he has suffered more or less pain since.

On his admission, the knee was swollen, had a globular shape, the skin not discoloured, the ham filled up. The part was painful when pressed upon, or when moved, more particularly towards the outside of the patella; it had an elastic feel towards the inside of the patella. He was unable to walk; the knee was semiflexed; the limb above and below the joint was emaciated. He was suffering from some constitutional disturbance; the tongue was red, and he had lost flesh. The countenance had an anxious expression, but nothing apparently indicating malignant disease.

After a time the integuments upon the outer side of the patella assumed a red colour, and there was a feeling of fluctuation at this part with pointing. The patient lay inclined towards the left side with the knee semiflexed. He complained of frequent starting of the limb, particularly when asleep, the pain of which was so severe as to awake him. On introducing a grooved needle at the point where the feeling of fluctuation was best marked, nothing but blood appeared.

Subsequently the limb became swollen above and below the joint; the surface of the tumour was marked with blue veins; it increased in size; the pains became more severe, the patient more emaciated, and he was occasionally delirious at night. About the end of May he was delirious also during the day, the fœces were passed involuntarily, and the patient died June 5th.

Post-mortem examination.—Body much emaciated; integuments covering knee pale, without any appearance of blue veins. On removing the integument covering the joint towards the inside of the patella, much subcutaneous fat came into view, and it was readily detached: on the outside it was very adherent and thinned. On making a vertical incision on the inside of the patella, from the tibia towards the femur, the knife penetrated through a great thickness of substance without opening into the joint, which cut like soft cartilage, and presented all the appearance of carcinoma. On the outside of the patella a similar incision cut through a considerable depth of a substance resembling a mixture of brain and blood. The cavity of the joint was almost obliterated. The lower extremity of the femur was completely disorganized and broken up. The popliteal vein was plugged up with a firm coagulum. The veins of the nerve here were much injected and tortuous. Some enlarged glands could be felt in the groin below Poupart's ligament on that side. All the organs in the abdomen were healthy. The left lobe of the liver had the nutmeg appearance, and a single small round tubercle, the size of the kernel of a hazel nut, was found in it. Some small tubercles were found in the lungs of apparently a similar character, and upon the pleura and the diaphragm many small elevations were seen. The heart was enlarged and flabby.

PROCEEDINGS OF SOCIETIES.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Dr. Begbie, President, in the chair.

ENCEPHALOID DISEASE OF LUNG.

Dr. Douglas laid before the society a preparation showing the effects of an encephaloid tumour in the upper and front part of the chest. Dr. D. first pointed out the seat of the tumour under the upper part of the sternum, extending to the left so as to occupy in part the left subclavian and mammary regions, firmly adherent to the parietes, and dipping between the pericardium and left lung; the contiguous part of which had become involved in the cancerous mass—specks of pulmonary tissue still appearing in the tumour at some depth from its surface, and infiltration of cancerous matter having occurred in the lung, beyond the more marked boundary of the tumour. In the upper part of the sac of the pericardium, to the left, the tumour presented several irregular nodulations, not as yet fungoid. In the recent state of the parts, the pericardium was distended by a large quantity of blood and serum; the tumour and left lung adhered, except at the lower part behind, where the sac of the pleura contained about a pint of serum; there were evidences of general bronchitis; the head of the pancreas contained a dense scirrhous tumour, as large as a hen's egg; emaciation was great; and there was considerable anasarca of the left upper extremity, and left side of the chest. The left carotid and subclavian veins were, at their origin, inextricably involved in the tumour; and they contained firm imperfectly decolorised coagula, which appeared to plug them up.

Dr. Douglas said he would not detain the society with a detailed history of the case; and, in the observations he

had to make, would confine himself to certain of the physical signs, which in thoracic tumours are variable and obscure, and which, nevertheless, constitute the chief data from which a diagnosis is to be formed. In the present case, however, the general or rational symptoms had afforded indirect but important information. Hæmoptysis had occurred at a very early date, above a year before the patient applied for relief, with cough and difficult breathing when she exerted herself; for a long period, also, she had suffered from fixed pain high up between the scapulæ, and deep-seated; at the same time the general effects on the rest of her system had been slight, contrasting with the severity and duration of the symptoms referrible to the organs of respiration; her pulse had not exceeded 100; and she had had no perspirations. From her own account, she had experienced more or less distress for two years before the symptoms became urgent, and two years and a half before her death. The chief difficulty in diagnosis had been to determine that the case was not one of chronic pleuro-pneumonia, with pulmonary tubercle; and the physical signs did not throw much light on this difficulty; while the early hæmoptysis. and the absence of these cachectic states of the system which accompany the diseases usually causing hæmoptysis, afforded only negative evidence of the nature of the case. Of the physical signs, Dr. D. drew attention to the absence of several which have been considered to be distinctive of such cases—the varicose state of the superficial mammary and epigastric veins; it was difficult to explain the want of this condition, and it would be found to be less invariably present than has been supposed. Dr. D. referred to the occurrence of distension and even varix of the superficial mammary veins in some cardiac diseases in which dilatation preponderates.

The jelly-like expectoration described in cases of pulmonary cancer, had not existed, probably owing to the extra-pulmonic origin of the tumour. The sounds of respiration had not been suppressed to any extent; harsh mucous rattles having existed in the subclavian region. Two of the most direct signs in the case had been the existence of a pulsation more forcible and extended than occurs in other forms of pulmonary consolidation, and the diminished vibration of the voice, which is for the most part increased by consolidation, and by compression from pleural effusion—cancerous consolidation, however, always causing diminished vibration in the part, and deep-seated tumours in compressing the bronchial tubes, certain aneurisms, for example, inducing suppression of the vibration throughout the side of the chest. In conclusion, Dr. D. directed attention to the following as the leading peculiarities of the case in its diagnosis:—The early occurrence of hæmoptysis and other local symptoms—the *general* effects of the disease, especially the want of frequency of the pulse and of perspiration being disproportionately slight; the peculiarities of the inter-scapular pain; the only physical signs of value being the *position* of dull percussion with pulsation and diminished vocal vibration.

CANCER OF THE LIVER IN A DOMESTIC FOWL.

Dr. W. T. Gairdner exhibited a specimen of disease of the liver in a duck, accompanied by enlargement of the absorbent glands about the gizzard and commencement of the intestine. The liver was much enlarged, and presented, both on the surface and on section, many distinct tumours strikingly resembling the tubercles of Farre in the human liver. They bore a similar average proportion to the bulk of the organ, being generally about three-eighths of an inch, or half an inch in diameter; they were more or less accurately globular, but most of them, where they appeared on the surface, were either flattened, or had a cup-shaped depression. They were on section like the firmer varieties of Farre's tubercle, in which partial drying up of the cancerous matter has taken place; the colour of a grayish white at the circumference, and ochrey tint towards the centre; the different tints being marked off from one another by irregular lines concentrically disposed. The microscopic appearances could not be satisfactorily made out, as the preparation had been placed in spirit some time before an opportunity of examining it was obtained.

URINARY DEPOSIT OF URATE OF SODA.

Dr. Gairdner also showed a specimen of urinary deposit, having the microscopic characters ascribed by Dr. G. Bird to urate of soda, but occurring in the urine of a patient suffering from pneumonia, and not taking any form of soda as a remedy. This circumstance justified doubts as to the nature of the deposit, which had not yet been submitted to analysis.

ARTIFICIAL NOSE.

Dr. W. A. Roberts exhibited a model of an artificial nose and palate. He stated that, at the request of Dr. C. Bell, he had attempted to construct an artificial nose and palate for a patient of his who had entirely lost the nose and a portion of the palate. After many attempts, he had at last succeeded by employing gutta percha.

The first step was to take an impression of the parts of the face with warm wax, and casting this with plaster of Paris, an accurate mould of the part desired was got. To this a nose of common wax was shaped and fitted; this wax nose was then carefully imbedded in plaster, the wax was melted out, and thus a counter mould was formed. He then got some whitened gutta percha, passed it through a pair of jewellers' rollers to bring it to the desired thickness of about a shilling; a piece large enough was first heated in warm water, then gently pressed into the counter mould; when cold, a form was given to it exactly the same as the wax model; this being carefully fitted to the face, a silver wire was attached to it on the inner side by means of a piece of heated gutta percha, the end of the wire was turned to a small ring to which a piece of fine sponge was sewn, sufficiently long to pass over the deficient portion of the palate. The palate, as usual, was made of gold, with a piece of sponge attached to the ridge, passing through the opening into the base of the lost nose. The nose was firmly held in its place by being pushed back close to the face, the palate being then put into its place, the sponge of the palate being in front of that of the nose held it in its place, the one supporting the other. The upper portion of the nose was held firmly to the face by means of spectacles having an elastic band going round the head. The nose was carefully coloured to suit the heightened spots and shades of the face, and when seen at a few feet distant, was hardly observable. The patient wore these helps till his death. The sponge was found to be of great comfort, by absorbing any discharge that occurred.

CASE OF MALIGNANT DISEASE OF STOMACH.

By Dr. Wilson.

The details of the following case are, I regret to say, so imperfect in many respects, that I should not have thought of submitting them to the society had I not been requested to do so by Dr. Gairdner, considering the case interesting in some respects in a pathological point of view.

The patient, an unmarried female servant, aged 63, had for upwards of twenty years suffered from dyspeptic symptoms—viz., more or less pain in the stomach, anorexia, and pyrosis. These abated considerably about two years ago, but within the last six months had become greatly aggravated, especially the pain at the stomach, leading her to hold her hands firmly over it with the hope of relief; she had also some difficulty of swallowing, and the attempt to do so often brought on vomiting, consisting partly of the food and a quantity of tough mucus of a slightly greenish hue. At the time I first saw her—viz., about three months ago—these symptoms continued, and led me to infer ulceration of the stomach in the vicinity of the cardia, and that most probably of a malignant character. The patient did not present much of the peculiar hue of malignant disease, and there was no tumour to be felt externally; the liver also was normal in size; the urine was not coagulable by heat, and the other functions were normal—heart, lungs, &c. The patient had some pills of aloes and iron to regulate the bowels, which were very constipated, Prussic acid, naphtha, and creosote, as also a blister, none

of which, however, succeeded in allaying the vomiting, which gradually subsided spontaneously, apparently from want of material, as the appetite completely disappeared, and she consequently became more and more emaciated, till she died on the 11th of June. A post-mortem examination was made on the 13th. Notwithstanding the emaciation, there was nearly an inch of fat beneath the abdominal integuments. On laying open the abdomen, there was observed a small tumour about the size of a nut, situated on the lesser curvature of the stomach; on attempting to remove the latter organ it gave way, and in doing so, displayed a mass of ulceration in the vicinity of the cardia. This was removed for examination, along with the uterus and ovaries, and was submitted to Dr. Gairdner. The spleen was healthy; the liver presented a nutmeg appearance when cut into. There was also a large mass situated along the spine, supposed to be of a cancerous nature, surrounding the spine, extending from the ninth or tenth joint to the lower curvature, and matting the vessels, &c., in that situation; the relations of which I now regret I did not examine more particularly. The kidneys were large, and rather congested; the lungs were healthy; the heart was loaded with fat.

The parts examined by Dr. Gairdner were the uterus, a portion of the stomach, and some of the adhering absorbent glands. The uterus presented a number of small fibrous tumours in its wall, producing considerable deformity of the organ; some of them had evidently undergone to a great extent the calcareous degeneration common in such growths. Several of the tumours, not exceeding the size of a pea, projected immediately beneath the peritoneum; one, which was equal in bulk to a small walnut, was attached to the exterior of the fundus uteri, by a pedicle three-quarters of an inch in length, and lay in the peritoneal cavity, free from adhesions, but considerably congested on its exterior. Two of the tumours were in the cellular tissue, in the neighbourhood of the neck and body of the uterus; they were evidently of long standing, being completely calcified; but whether they had originally arisen in this part of the wall (which was a rare situation for such tumours), or in the fundus, it was not possible to form a conjecture, as they were totally detached from the uterine wall. The cervix and os appeared to have been normal, but were injured in removal; the ovaries and Fallopian tubes were healthy.

The portion of stomach removed presented no distinctly cancerous appearance; the attached glands were large, soft, friable, and contained a whitish creamy juice which showed large and highly granular nucleated cells under the microscope. Though these were not characteristic of a cancerous structure, yet it is impossible, viewing these facts in connexion with the enormous tumour recorded by Dr. Wilson in his account of the dissection, to doubt that these glands formed the appendages of an encephaloid mass overlying the vertebræ.

In this point of view, Dr. Gairdner observed that the case was interesting, as showing how very little tendency these fibrous tumours have to undergo any malignant degeneration, since they were found in the present instance to exist in every stage of development and of transformation into calcareous matter, without the least trace of cancerous structure in or around them. Cruveilhier, indeed, believed that the fibrous tumour of the uterus, or of any other part, conferred a comparative immunity from cancer of the same organ, and that these tumours themselves never underwent this degeneration. Dr. Gairdner, however, had seen, in the museums both of London and Edinburgh, specimens opposed to this doctrine, in which the uterus, manifestly cancerous, contained also fibrous tumours, and these were undergoing at some points, fusion into the mass of cancerous tissue.

CASE OF ANEURISM OF THE THORACIC AORTA, WITH OBSERVATIONS ON THE PROPRIETY OF PERFORMING TRACHEOTOMY IN SOME CASES OF ANEURISM.

Dr. W. T. Gairdner read a case of aortic aneurism, which presented the following peculiarities:—The sac, about the size of a walnut, arose from the back part of the arch, which was but slightly dilated; the tumour pressed upon the left recurrent nerve, and had in this way determined frequent attacks of orthopnœa, with laryngeal obstruction; at the same time that there was no evidence nor appearance of serious pressure upon the air-passages. The aneurism had opened into the trachea, but without important hæmorrhage; nothing but a tinge of the expectoration had resulted, the sac being full of coagulum. There was no physical sign of the presence of a tumour, and the aneurism remained undiscovered till the patient's death, which occurred, not from hæmorrhage, but from spasmodic suffocation. Tracheotomy was projected from the first, and repeatedly urged, but the patient would not submit to it until he was moribund, when accumulation in the bronchi had taken place to such an extent as to render it unavailing.

Dr. Gairdner discussed several points in the pathology and diagnosis of this case, and concluded by observing that the state of the parts as found after death, fully justified the attempt to relieve the patient of his distressing symptoms by tracheotomy. He argued that, there was distinct evidence of the frequent termination of aneurisms in this situation by spasmodic laryngeal suffocation; and under such circumstances, if it was ascertained that the lower air-passages were tolerably free from impediment, he thought that tracheotomy was not only justifiable, but imperatively demanded as a means of prolonging life. That the operation of tracheotomy might have the effect of prolonging existence, even in aneurisms more advanced, and circumstances far more desperate than the present, was proved by a case recorded in the *Lancet* for 1844, in which Mr. Judd performed it upon a patient in articulo mortis, with the effect of prolonging life thirteen days, although a large aneurism of the aorta had been pressing upon, and had burst into the trachea, causing hæmorrhage to the extent of thirteen ounces. And although few would be inclined to covet an opportunity of following this practice under the like circumstances, the case was instructive as pointing out how much might be done for the relief of those in whom the symptoms were chiefly or exclusively laryngeal. At all events, as the propriety of tracheotomy in aneurism was not, so far as he knew, formally recognized by any authority, and as in several well known works it appeared to be discouraged, or even viewed as unjustifiable, Dr. Gairdner had thought it his duty to lay the subject before the society, with the view of eliciting the opinions of members present.

Dr. Seller thought that the presence of an aneurism should in general counter-indicate the operation. In this particular case, however, had Dr. Gairdner been allowed to act at an earlier period, the life of the patient would in all probability have been prolonged. But he repeated his conviction that tracheotomy, though justifiable in this case, was not applicable in cases of aneurism in general.

Drs. Keiller and Andrew, who had had the care of the patient before Dr. Gairdner took charge of the case, had detected no physical sign of aneurism, and quite concurred in the propriety of performing tracheotomy.

Professor Miller concurred in the main with the statements of Dr. Gairdner, and thought that he had laid an important as well as interesting communication before the society. Cases of aortic aneurism, with reference to the performance of tracheotomy, seemed to be divisible into two classes. 1. Those wherein the tumour was so circumstanced in situation and bulk as to compress the air-passage, narrowing its calibre, and producing a permanent obstruction to breathing. In those the dyspnœa would be continuous; liable, it may be, to aggravations and remissions, but never wholly absent; and, in most examples also, diagnosis both as to the existence of aneurism and of such mechanical interference with the air-passage, would not be very difficult to the experienced and careful observer. In such cases he would be inclined to refrain from operation, anticipating little or no benefit from it, even of a temporary kind: and fearful lest, by obvious failure, the

department of operative surgery should be brought into discredit. Into this class the melancholy case of the late Mr. Liston, alluded to by Dr. G., evidently came; the windpipe compressed, the breathing continuously laborious, and no likelihood of satisfactory relief from artificial opening of the windpipe. The case quoted by Dr. G. from the *Lancet* might seem to oppose this opinion. But he (Professor Miller) felt inclined to regard that case as quite an exceptional one. The man could breathe only through a small tube or catheter thrust down from the wound past the aneurismal swelling; and that tube—so small, so liable to displacement, so liable to obstruction, so certain to cause advance of ulceration in the part of the tumour on which it lay—seemed to him too miserable and slender a tenure of existence to warrant its being had recourse to with any hope of success. It was only surprising that through such a precarious access to the lungs, the man continued to live so long. 2. The second class included those cases in which the tumour, not so large as to compress and narrow the air-passage, is yet so circumstanced as to affect the larynx dangerously; as in Dr. Gairdner's case, irritating or compressing the recurrent branch of the eighth nerve, so as to excite paroxysmal attacks of intense laryngeal dyspnœa, similar in their nature to those of laryngismus stridulus. These tumours, from their small size and deep locality, would be difficult of detection; and yet there were means, too, as Dr. G. had shown, both positive and negative, by which their existence might be at least strongly suspected. And, under such circumstances, he (Professor Miller) would have no hesitation in saying, as his own belief, that—provided the paroxysms of dyspnœa were such as to threaten instant extinction of life—he would have recourse to tracheotomy at a comparatively early period of the case, not waiting till the patient was in *articulo mortis*; and for the following reasons:—The operation in itself was not formidable, not difficult of performance, and not dangerous to life. By having recourse to it, he would relieve the patient at once from intense agony and suffering. Besides, at comparatively little cost, he would prolong existence—for hours, weeks, or months; and all well knew how vastly important even a comparatively short period of reprieve might be found to be under such circumstances. Further, it was not wholly utopian to suppose that such relief and prolongation of life might, in some rare cases, contribute towards the actual occurrence of spontaneous cure. In listening to the details of the post-mortem examination in Dr. Gairdner's case, one could not fail to be struck with the near approach made in that case to cure. The small aneurism was almost entirely filled with clot, and the oval aperture by which it communicated with the aorta was almost wholly obstructed by a mass of fibrin. Very little more might have silenced the tumour. And that little might have been greatly contributed to by the relief of respiration afforded by tracheotomy timeously performed; while, on the other hand, the oft-recurring attacks of dyspnœa, with the attendant excitement and distress of the patient, could not fail not only to oppose all attempts at spontaneous cure, but also to hurry on the fatal advance of the tumour. Hitherto his creed had been—(he had taught it in his class, and published it in his System of Surgery)—in regard to the performance of tracheotomy in connexion with aortic aneurism, that the operation should not be had recourse to, the cause of the suffering being apparently beyond relief by tracheal wound. But now he was bound to say, that he saw reason to alter that opinion, and to hold that, while the rule of non-interference still held good in the first class of cases which he had specified, in the second there was not only a warrant but a call to operate, with the hope of certainly relieving suffering and prolonging life, and with the chance of even contributing towards the occurrence of spontaneous cure. There might be a third class of cases (as suggested by Dr. Gairdner) in which pressure on the windpipe was slight, but yet with a certain degree of contraction of its calibre, and in which *paroxysmal* laryngeal dyspnœa was also urgent. In such circumstances he would hold that the latter part of the case, or major, would rule the former part, or minor; and that, therefore (more especially if urged to it by the patient), he would be inclined to operate, though, of course, with a less favourable prognosis than when no compression and contraction of the windpipe existed. On the whole, he considered that Dr. Gairdner had made an important contribution to practical surgery; extending its operative interference to a class of cases—few in number, doubtless, and not holding out much hope of permanent benefit—hitherto supposed by many to be excluded from its range. It was the province and duty of the surgeon, as well as the physician, to palliate by every reasonable means where he cannot cure; and if unable to save life, at least to protract and soothe its closing day.

After some remarks by Dr. D. Maclagan,

Dr. W. T Gairdner said that he had alluded to Mr. Liston's case as conclusively showing that an aneurism of the aortic arch might remain without physical signs, or, at all events, might present an extremely obscure diagnosis, up to a period when it had threatened life by one or other of its secondary accidents. The present case, as well as others, proved that spasmodic dyspnœa, a frequent cause of death in aneurism in this situation, might occur and prove fatal while the air-passages were exempt from pressure; and while the larynx, involved through its nerves, was the sole cause of dangerous symptoms. In such a case, the practitioner was surely not warranted in making the probable or certain fatality of the disease an excuse for non-interference, especially when the operation was one not in itself dangerous, and almost certain to secure to the patient not only a comparative immunity from distressing symptoms, but a longer lease of life and a slower progress of his disease. Nothing was more likely to accelerate the increase and fatal result of an aneurismal tumour than the violent inspiratory and other efforts which accompanied the paroxysms of stridulous breathing in these cases; and if these paroxysms could be entirely removed in many cases of aneurism by so simple a proceeding as tracheotomy, it would surely be allowed that this operation presented a fair claim to be admitted into the legitimate treatment of such cases; and to be resorted to, not unwilling and as a last resource, but *as early as it could be ascertained that laryngeal symptoms were the source of the more immediate danger*. No doubt the operation became less and less eligible in proportion as *other* sources of danger became imminent; but so long as these did not reduce the laryngeal symptoms to a manifestly secondary importance, Dr. G. did not feel that he would be justified in refusing to a *willing* patient, *after due explanation*, the chance of life and comparative comfort for an additional day or hour. The amount of pressure of aneurism on the air-passages could always be estimated by careful stethoscopic examination with considerable precision; as though other sources of danger might remain unknown, the fact ought not to be made an argument against interference for the removal of the palpable and imminent hazard. And if these rules of conduct were sound when an aneurism was *known* to exist, they were all the more evidently so in the case where such a tumour was only suspected, or where, as in the present case, the suspicion had been allowed on the strength of negative evidence, to drop too hastily from the mind.

An authority so justly and so universally known as Dr. Watson, had stated that no man with a stethoscope in his hand, and the power to use it properly, ought to be seduced into the error of performing tracheotomy in a case of aortic aneurism. If the principles adopted by him (Dr. G.) were correct, there was here an opinion extremely calculated to mislead; and no doubt there were many physicians who would be alarmed at the idea of opening the trachea, not for a laryngeal, but for a thoracic disease. For his own part, Dr. G. had no desire to screen himself from criticism, if it was thought that by any reasonable precaution, a correct and secure diagnosis might have been formed in the present case; but on general, and not on

personal, grounds, he thought that a different bias ought to be given to the practical precepts current on this subject, and that practitioners should neither be taught to be too sure of the diagnosis of thoracic aneurisms, nor too apprehensive of the performance of tracheotomy.

CLINICAL MICROSCOPE.

Dr. W. T. Gairdner showed a very convenient and generally useful microscope which he had recently had constructed by Mr. James Bryson, and had already employed sufficiently to be convinced of its great superiority, for most purposes of the practitioner, to all the portable and pocket-instruments now in use. It consists of a simple but very carefully ground Coddington lens of small size, and magnifying about 180 diameters, set in a convenient handle and adjusted to a shallow cylinder of silver, which at one end embraces and surrounds the setting of the lens, and at the other bears a small plate of glass for the object, which may, if necessary, be covered by another glass. The instrument is raised to the eye opposite a moderately strong light, and the object is focalised by a screw fixed in the handle, and bearing on the spring by which the silver cylinder is kept close to the lens. The instrument can be managed conveniently with one hand; and as it is considerably shorter, and not much thicker, than an ordinary pencil-case, it may easily be adapted, if requisite, for the pocket. It distinguishes readily all the ordinary urinary deposits, and, to a practised eye, suffices in ordinary cases for the examination of blood, pus, and most of the elements of the tissues; although for delicate observations a higher power is of course requisite. Perhaps the greatest recommendation of this instrument is the ease and comfort with which it can be used; the examination of a fluid being at once effected by dipping the glazed end of the silver cylinder into it, or placing a drop on the outer surface of the glass; then on shaking off the superfluous moisture, and raising the instuument to the eye (at the same time using the focal adjustment), the fluid is seen to float down the glass, bearing constantly renewed objects over the field of the lens, and enabling a rapid and effective survey of the contents of the fluid to be made in much less time than it could be done by a compound microscope with a large field, even if ready on the spot for action.

UNCONTROLLABLE SEXUAL APPETITE IN A CHILD FIVE YEARS OLD.

By J. Haines, M.D., of Keobuk (British America).

Permit me through your journal to make known to the medical profession my experience and observations of an extraordinary case, hoping that the subject of my remarks may not prove unprofitable or devoid of interest:—The patient is a female, a little over five years of age, very fair complexion, light coloured hair, blue eyes, veins deep blue and very superficial, general contour good, and naturally a sprightly, interesting, and affectionate child. While absent from her parents on a visit to see her relatives, living in the State of Kentucky, more than a year since (then not being quite four years of age), she says the children of a neighbouring family taught her this habit. Her story is, "a family lived near to us, where there were several little boys and girls; they all practised this habit frequently every day, and taught it to me. At first it gave me pain, and I did not like to do it."

From the best information I can get, her progress was rapid, and since the habit has become confirmed, she has indulged daily, and oftentimes to great excess; from that time to the present, she has frequently exhibited symptoms of mental derangement.

March 23, 1851, I was consulted as to the best mode of affording relief. Having had some experience in trying to manage patients addicted to this destructive habit, I at once expressed to the parents my [illegible] of the result, and apprised them of the difficulties to be encountered.

A thorough examination was made. Pressure over the region of the ovaries elicited no pain, and no unnatural or extraordinary development of the genitals or mammary glands existed. The vagina was explored (and has been frequently since); no ascarides, pruritus, or any other source of excitement could be detected; the general health was good; the bowels were regular; digestion perfect; pulse 75 and 80; the patient never has been much sick.

From 23rd of March to May 20th, nauseates, anodynes, cold hip-bath, hip-bath with sulph. potass., cauterization of the clitoris, blistering of the genitals, mercurial alteratives, mechanical and moral restraint, &c. &c., were studiously administered, and failed to produce any mitigation of the propensity. During this time she was confined to a low diet, also took freely, at one time, anthelmintics, producing the expulsion of four worms (ascaris lumbricoides).

At times when the labia majora, minora, and clitoris were an entire raw surface from the application of blisters, caustic or antimonial ointment, she would frequently steal the opportunity to manipulate, and would gratify her desire though the pain or soreness were very great. Often she would cause considerable hæmorrhage from the raw surfaces. When long prevented (say for one or two days), by close watching and restraint, she would become almost frantic, thrusting her fingers into the nostrils, causing her nose to bleed, pull at her hair, pinch her ears and hands, especially between the fingers. A dark areola beneath the eyes, talking incessantly, unusual acuteness of audition, aversion to encounter the gaze of any one when spoken to, inability to concentrate the mind on any subject other than such as is connected in some way with this self-gratification, ever deceitful in the extreme, are the principal diagnostic indications.

Her general health is remarkably good; digestive powers strong; even when emesia is produced as often as five or six times a day, she will eat heartily in the intervals if allowed; the elimination by the kidneys is normal; her manners, mode of indulging, appearance when experiencing the effect of self indulgence, and her advances and deportment towards the male sex near her own age, leave no doubt as to the particular nature of this morbid passion.

Despairing of managing my patient successfully, and having availed myself of all the medical advice I could get from my professional brethren, on the 26th of April I addressed a communication to Dr. Allen, superintendent of the Lunatic Asylum, Kentucky, requesting the privilege of placing her in the care of that excellent institution. Owing to the "crowds of patients in the wards" at the time, this unfortunate child could not be received. For the valuable suggestions on the treatment of such cases contained in Dr. Allen's kind reply, I tender him my sincere thanks. All treatment was suspended from the 20th to the 31st of May, when I again, at the earnest solicitation of the parents, recommenced treating her.

From 31st of May to the 15th of June, I endeavoured to control her by operating on the moral faculties alone. For a few days I think her mind improved, the dark ring below the eyes disappeared, and she was less inclined to converse with others, but when alone talks constantly to herself.

On the 15th and 16th being professionally engaged, so as to preclude my giving her that attention to which she was accustomed, I discovered she looked much worse, areola about the eyes much darker than usual, her face flushed, and she was nervous, excited, and shy. On examination I found the genitals very red and swollen. She confessed to having indulged some ten or fifteen times the day previous, said she could not count more. On June 17th, she was put on nauseates and anodynes, also same day, cauterized the clitoris freely, which inflamed and became exceedingly painful; yet up to this time (June 21st) she has managed to gratify her passion several times, although the antimony (used as a nauseate) and anodynes have been administered daily.

When first detected in this habit she used her hands. They being confined, her legs were crossed; they next being retained apart, she acquired such control over the abdominal, perineal, and gluteal muscles, as to answer all

necessary purposes in the gratification, either lying, standing, or sitting. The mucous surface of the labia becomes quite moist or "wet," to use her own language, at each excitement.

At my first interview with this child, she expressed an anxious desire to be freed from this habit, said she prayed daily for relief, but at present appears quite unconcerned about it. The circumstances in this instance being such as to preclude the possibility of exercising moral restraint, or of obtaining assistance from her own endeavours, make the result of any treatment extremely problematical; in proportion to the morbid increase of her passion seems to be the decline of moral power. Reason being dethroned, moral and intellectual chaos reigns, where once it shone beautiful in juvenile simplicity.

Remarks.—The erotic influence on the physical organism is so perfect, and when abused, so powerful, as to be capable of germinating disease of every organ of the body. There are few diseases to which flesh is heir that may not be developed by this species of dissipation. The nervous centres are usually the first to take on diseased action where no predisposition exists in other organs. Radiating from these centres, we have partial or general paralysis, tetanus, incontinence of urine, chorea, epilepsy, apoplexy, caries of the spine, melancholy, vertigo, loss of sight, emaciation, dementia, idiocy, &c. If we are to credit writers upon this subject, almost the entire catalogue of diseases known to the scientific pathologist are liable to arise from this species of dissipation, and an accurate knowledge of its connexion with constitutional and local disease, it is of the utmost importance in arriving at a correct prognosis.—*Western Medico-Chirurgical Journal* and *British-American Journal.*

We feel some reluctance in giving publicity to this very remarkable example of precocious development of this function, from an apprehension that by so doing discussions may arise of a nature very different from those which scientific inquiry suggest; but the subject is one which cannot be overlooked by the physiologist, however illsuited to more general inquiry. The use made of the facts which experience proves really result from a study of this subject, has undoubtedly deterred many practitioners from taking part in the discussion of it; few men being willing to appear in any way engaged as the infamous parties are who disseminate obscene advertisements. The necessity of an adequate acquaintance with such source of formidable disease, however, renders a guarded allusion to it necessary, and therefore do we place this example on medical record.

TÆNIA SOLIUM—RELAPSE AFTER THE USE OF THE KOUSSO.

Under the care of Dr. Wilson.

Case 1. Harriet W——, a dark good-looking girl, aged 16, was admitted into Queen's ward, September 10, 1851, under the care of Dr. Wilson. This patient has been living for some years at Portobello-terrace, Bayswater, and has been troubled with the tape-worm for a long period. About four months ago, she took a full dose of turpentine, which had the desired effect; the patient passed a worm which measured nine feet in length. She then had a little rest, but she soon began again to pass fragments of the worm, and she now entered the hospital in order to get rid of the parasite altogether.

The girl presented the usual symptoms of tape-worm, and Dr. Wilson prescribed a dose of kousso to be taken on the second morning after admission. It was taken fasting, and the effect was produced in a very short time. The patient soon evacuated a worm measuring about three feet in length, but the head was not noticed to be attached to it. The kousso used in this instance, and in the two cases which we subjoin, was procured at Mr. Savory's in Bond-street.

Case 2. James A——, aged 21, a dark and robust-looking young man, and a shoemaker by trade, was admitted September 10, 1851, into Grosvenor ward, under the care of Dr. Wilson. The patient is a native of Eaton, but has lately resided at Northampton. One year and a half ago, he first began passing fragments of the worm; these used to be expelled unknown to the patient, as he was sometimes surprised to find them about him. He took large doses of turpentine, but these did not promote the expulsion of the worm. At last, when at Windsor about ten weeks ago, he applied to the dispensary, where he was administered a dose of the patent kousso. This medicine caused the evacuation of a worm, seventeen or eighteen feet long; and after this relief he soon gained flesh, and the knawing sensation at the pit of the stomach, and a peculiar debility and nervousness, left him. This favourable state of things did not, however, last long, fragments were again passed, and he now sought relief in this hospital. Dr. Wilson ordered five grains of calomel at bedtime, and castor oil in the morning, for the first day; and on the subsequent one the patient took six drachms of kousso while fasting. Some hours afterwards he was given infusion of senna with sulphate of magnesia, and though the stools were abundant, no appearance of the worm was noticed in them, except a few scattered fragments. Thus it might be surmised that the kousso failed in this case to have the usual effect.

Case 3. John G——, a short dark man of sanguineo-nervous temperament, and a tailor by trade, was admitted into Grosvenor ward, September 10, 1851, under the care of Dr. Wilson. The patient has always resided at Slough, is married, and of temperate habits. About four years ago he began to notice joints of the tape-worm, which he used to find about his legs and his shoes as he walked along; his principal symptoms were sinking at the pit of the stomach, and a voracious appetite. About eight months before admission, the patient took a dose of the kousso at the same dispensary of Windsor as the man mentioned in the preceding case; this brought away a worm twenty-seven feet in length, and this evacuating gave him much relief. He had now rest for nine weeks, when he began passing joints again, and this circumstance induced him to come to London. The patient was then admitted into this hospital under the care of Dr. Wilson. He took the kousso again, and this caused the evacuation of a tænia of the same length as the first. The man soon returned home, and perceived no symptoms of the worm until a few days before this, his second admission, when the joints appeared again as heretofore. Two days after his second entrance into the hospital, he took the usual dose of kousso, the bowels having been cleared with castor oil on the preceding day, and as it did not act for five hours, infusion of senna and sulphate of magnesia were administered; patient then passed a worm of a very great length. Here we have, then, three cases of relapse, the first (a girl) after taking turpentine, and the two others, in spite of regular doses of the patent kousso. These facts may justly be considered of great value, because a remedy can never take a firm footing, and cannot be implicitly trusted unless the patients who have used it have been watched for some time afterwards.

The third case is the more valuable as the patient has now taken the kousso three times—once at Windsor, and twice under Dr. Wilson. As to the second case, it remains of course a question whether there really exists a worm, or whether the dose of the medicine was not sufficiently large. Nor is the case of the young girl devoid of interest, for it affords a proof that, as far as the expulsion of the tænia is concerned, turpentine and the kousso act pretty well in the same manner. We heartily could have wished, for the benefit of the afflicted, that the Abyssinian remedy had had the property of radically curing the disease; it should, however, be mentioned, that of all patients whose cases we have from time to time reported, none have, to our knowledge, applied again for admission into the hospitals where the remedy had originally been administered.—*Lancet.*

TOPICAL APPLICATION OF CHLOROFORM.

By Dr. Rauch of Burlington, Iowa, United States.

While I was attending the clinical lectures at the Pennsylvania Hospital during the winter of 1848 and 1849, the attention of the class was called by Professor Wood, who was then the attending physician, to a case of facial neuralgia, which had proved rebellious to the ordinary remedies. In this case, the Professor prescribed the topical application of chloroform, with the most decided relief to the patient, at the same time stating that he had been led to do so by the favourable report of Dr. Hays, who had made use of the application in a similar case with the most happy results. This was the first time I witnessed the external application of chloroform for the relief of neuralgia. During the summer of 1849, I had various opportunities to test its merits in relieving pain of that character, the results of which were satisfactory.

From that time until the present, I have almost daily made similar applications, with nearly the same result. In some instances the relief did not prove permanent, but all that was necessary in such cases was a repetition of the application. Generally speaking, I found that it gave relief to all headaches not dependent upon a derangement of the *primæ viæ*, and to all pains not very deep-seated. When first applied (so as to prevent its evaporation), it produces a cooling sensation, followed by a feeling of warmth, which is gradually increased to a sense of burning and smarting, which, however, is easily bearable. It produces redness of the part to which it is applied, which is speedily dissipated upon the removal of the cloth, leaving the skin harsh and disagreeable.

Owing to the sudden evaporation of the chloroform, its transient effect, and the roughness and harshness of the skin that were produced by its application, the idea of incorporating it with some other substance that would obviate these objections to its external application occurred to me. In olive oil, I found this desideratum. To effect a more minute union of the oil and chloroform, I added aqua ammoniæ, which produced a beautiful milky white emulsion, nearly similar to the volatile liniment, but not so consistent and white. The addition of the aqua ammoniæ seems to add to the efficacy of the chloroform, at least its counter-irritant effect is increased by it. So far, all succeeded admirably, and it only remained for me to give it a trial; an opportunity offered in the person of an "old lady," upon whom I had operated for cataract, who, in consequence of being compelled to remain in a recumbent position, after a few days complained of a severe pain in the small of her back. A woollen cloth was saturated with the liniment, and applied by means of friction; in a few moments the pain ceased and never returned.

Besides the advantages already stated of this preparation, it is not so expensive as the chloroform alone, and according to the result of my experience it is more efficacious, giving relief sooner, and its effects are not so volatile. The proportions in which I employed the different ingredients at first were equal, but afterward I graduated them, according to the effect desired. When I desired a powerfully counter-irritant effect I increased the quantity of ammonia and chloroform, and diminished the oil, and *vice versa*. In some instances I have been deceived as to its results, owing to the chloroform being of an inferior quality, and the aqua ammoniæ of not sufficient strength. Care must also be taken that the oil is not rancid, as it may nauseate, especially when it is applied to allay nausea and irritability of stomach. I applied it by means of a woollen cloth, folded in such a manner that the internal folds were completely saturated with the liniment, while the external were dry, thus preventing its evaporation. Oil silk cloth has been recommended by Dr. Hays to be placed over the saturated cloth, when chloroform alone was applied, but this is not always at hand, thus making the cloth prepared in the manner stated preferable. Immediately after the cloth has been saturated with the liniment, it is to be applied. At first it necessarily feels cool, followed in a few moments by a sense of warmth, which increases until it smarts and burns so severely that it can with difficulty be borne, continuing to increase for the space of about ten minutes, when it gradually diminishes, and is followed by a pleasing coolness, and, if there was pain in the part, with relief of it. When the application is found to cause more pain than is agreeable to the patient, it can be removed, or its position changed. Upon removal of the cloth, the part is found red, and in many instances vesication takes place. When it is desirable to produce mere rubefaction, it is sufficient to apply it by friction, or to allow the cloth to remain but a short time, as vesication will take place if allowed to exhaust its strength. This is not always the case, as it will depend to what part of the body, and to whom it is applied, the skin being more delicate in some than in others. If the pain should continue, it will be necessary to repeat the application. It will be seen that it combines a rubefacient and powerfully counter-irritant effect with an anodyne. Where a speedy effect is desired, it is far more beneficial than either a sinapism or blister, and is easier of application, especially in children, where great difficulty is experienced in retaining a sinapism or blister a sufficient length of time to produce the desired effect, in consequence of their screams and endeavours to remove them. The relief of the pain, and the slight inhalation of the chloroform escaping from the cloth, produce such a pleasing sensation, that I have often seen patients fall asleep immediately after its application.—*Amer. Jour.*

PECULIAR AFFECTION OF THE SHOULDER-JOINT.

By Sir B. C. Brodie, Bart.

Sir Benjamin describes a most tedious and annoying affection of this joint, seeming to depend in many instances on a chronic inflammation of the substance of the deltoid muscle, or of the bursa under the deltoid, and to be greatly benefited by the employment of counter-irritation and the iodide of potassium:—"The cases here referred to occur more frequently in private than in hospital practice; and (whether it be accidentally or not I do not know) it certainly has happened that I have met with it more frequently in the female than in the male sex. The patient complains of pain, which however is referred not so much to the joint itself as to the arm a little below it, near the insertion of the deltoid muscle. At first the pain is trifling, but it soon becomes severe and constant. The patient describes it as a *wearing* pain, of which she is constantly reminded. It is aggravated by every motion of the limb, and by pressing the articulating surfaces against each other. Not only is there no perceptible enlargement of the shoulder, but after some time, in consequence of the want of use and wasting of the deltoid muscle, it seems to be actually reduced in size. It is not long before the mobility of the joint is impaired, becoming gradually more and more limited. When the patient attempts to raise the elbow from her side, it is observed that the scapula is elevated at the same time with the humerus. She is unable to raise her hand to her face, nor can she rotate the limb so as to place it behind her. When the progress of the disease is stopped at an early period, the mobility of the joint may be restored; but otherwise, although the pain and all other symptoms of the disease have subsided, the joint remains stiff, and to all appearance completely anchylosed. Whatever motion the arm is capable of, under these circumstances, depends not on the humerus, but on the scapula; and it is remarkable to what an extent the scapula, or rather the muscles belonging to it, will accommodate themselves to this new state of things, so as to make up for the deficient motion of the shoulder. It certainly is seldom that this disease terminates in abscess of the joint, when proper attention has been paid to the treatment of it, nor has this happened in any case in which I have had the opportunity of closely observing its progress. I have, however, seen cases of abscess with ulceration of the cartilages, and complete destruction of the shoulder-joint, in which I conclude that, if I had been consulted at an early period, I should have found the symptoms to correspond with those which I have

just described. Whether it be from this, or from any other disease, that the joint of the shoulder is brought to such an extreme state of disorganization, one result is, that it is liable to dislocation, or, more properly, to sub-luxation in the direction forwards. In one case, in which I had the opportunity of examining the parts after death, I found the anterior margin of the glenoid cavity of the scapula destroyed by ulceration, the head of the humerus permanently resting on the ulcerated surface. In another case, in the living person, I found the dislocation to be only occasional, the head of the bone slipping forward so as to make a visible projection in certain motions of the arm, and in certain other motions returning to its natural situation. I may take this opportunity of noticing another circumstance, which, though not of much interest in pathology, is of some importance in practice. An abscess originating in the shoulder-joint sometimes presents a peculiar appearance, when it is making its way to the surface. A dissection, which I once had the opportunity of making, will explain at once the nature and the cause of this peculiarity. The abscess taking the course of the tendon of the long head of the *biceps flexor cubiti* muscle, had suddenly emerged from the joint at the lower end of the bicipital groove of the humerus: then, having taken a direction forward, on the anterior edge of the deltoid muscle, had presented itself under the integuments, having a spherical form, so that it might have been mistaken for an encysted tumour. I met with one case, in which this mistake respecting an abscess of this kind, was actually made by a surgeon of considerable experience, who proposed the removal of the tumour by the knife."—*Brit. and For. Med. Chir. Rev.*

THE SWEATING-SICKNESS AT CASTANDET (LANDES.)

By Dr. Dupouy.

In the month of April, 1849, an alarming rumour spread through the canton of Grenade, that a new disease, rapid in its progress and fatal in its results, had appeared in the commune of Castandet. This commune contains a population of from a thousand to twelve hundred souls. It is situated on a tolerably raised plateau; its soil is argillaceous and impermeable; it presents here and there small valleys, formed between hills of but slight elevation. The inhabitants are scattered over the district. The greater number are potters; they live almost like savages, their huts being always full of smoke from the fire, which is made in one corner without a fire-place. Their general want of observance of hygienic rules is in harmony with this state of living.

The panic was not without foundation. In the first three days twelve persons died, and several of these, within the first twelve hours of the appearance of the disease. The following is a sketch of the symptoms that were observed:

All complained of headache, and a feeling of soreness in the limbs; all were covered with a profuse sweat; all had a full and frequent pulse; all complained of a feeling of præcordial constriction, which gave place to the most painful anxiety. Occasionally this sense of oppression was felt in the epigastrium. All experienced thirst; the tongue was moist and red. In a large number an eruption was observed, variable as to its invasion, form, course, duration, intensity, and termination; it appeared on the face, neck, and chest, and on the inside of the arms and thighs. These were the essential or characteristic symptoms by which it was known that the disease was sweating-sickness: besides these, there were various accessory symptoms. Frequently the patient was seized without any premonitory signs; generally a rigor took place, most frequently at night or late in the day. The two extremes of childhood and old age seem to have been exempt from its attacks. Nearly all the patients were from 25 to 30 years of age. Seven-tenths of the patients were females. The duration of the disease varied from four to eight or nine days, according as the cases presented or did not present the eruption. The maximum intensity of the epidemic was exhibited at its first invasion, for the deaths occurred on the first, second, and third days. On the fourth day upwards of a hundred and fifty persons were attacked, in a population of a thousand or twelve hundred souls. The epidemic was confined to the commune of Castandet, with the exception of twelve persons who were attacked in the adjoining commune of Maurin. In the commune which it had chosen as its especial seat, it did not attack indiscriminately, but observed a course from east to west. It appeared (so to speak) like the sudden outburst of a waterspout: scarcely were five days passed from its first manifestation, and it had ceased.

To return now to the consideration of its characteristic symptoms. The *sweat* was constantly observed; it appeared with the fever. In some it was so profuse as to soak the bed linen; in others it only kept the surface of the body damp. In all it had an undefinable odour, the stronger the more abundant the sweat. The *eruption* was not so constant as the sweat, but was generally in proportion to the abundance of the latter. Only one case of confluent eruption was seen without the sweating, and that was in the case of a pregnant woman. In general the eruption appeared on the first day; in some on the second or third day. In a few cases it failed to appear, and the patients died. In a large number of cases spots resembling measles also appeared. There were generally seen minute vesicles of the size of millet seeds, white, opaque, sometimes purulent; so that by many persons it was named *white variola*. Four or five days after their appearance they lost their transparency, dried, and fell off as small pellicles. In some the period of desquamation was wanting; this was observed in those cases attended by the rubeoloid rash.

The chief point in the treatment was to favour the production of perspiration. Bleeding was tried with success at the first, but only at first. Quinine was of no service. Dr. Dupouy regards the disease as *sui generis*, and not an epiphenomenon in the course of another disease, according to Chomel's view: in the course of the epidemic now under notice, no symptoms of any other malady could be discovered.—*Med. Gaz.*

EXPERIMENTS ON DECAPITATED CRIMINALS.

By M. Duval.

M. Duval, from his position as teacher of anatomy at Brest, enjoys frequent opportunities of examining the bodies of culprits executed by the guillotine. The theatre of anatomy is so near the platform that the bodies are received within five minutes of decapitation. Among the facts which he has ascertained are many which bear upon points in physiology, still *sub judice*. The following are the results of the first examination recorded in the *Gazette Médicale* of July 12th: A man was decapitated for murder, and the corpse was brought to the table in less than five minutes. The first thing which attracted notice was that the divided extremities of the carotid arteries were projected in successive jerks, at the same time ejecting small quantities of blood. The jugular veins bled continuously. No reflex action could be induced by any pinching, or other mechanical irritation. After devoting a quarter of an hour to the opening of the abdomen, the chest was laid open, and the heart was seen beating with great distinctness; the left auricle, in particular, exhibited strong and perfectly regular action forty-four times in the minute, and continued to do so for an hour. Before the chest was opened galvanism was applied to the spinal marrow, and immediately caused movements of expiration and inspiration, accompanied by a hoarse noise in the larynx. After opening the chest galvanism was applied to the intercostal muscles, and caused the ribs to approach each other in a notable manner. The stomach was full of food; but none escaped after its removal, in consequence of the rigid contraction of the cardiac and pyloric orifices. The bile was dark green, and of a gummy consistence. The spleen was empty and wrinkled, and could not be made to contract under galvanic action; but the ureter contracted manifestly. The spermatic vesicles were filled with a liquid fluid, containing living spermatozoa. In another case the pupils were contracted by galvanizing the third pair of nerves in the cranium.—*Prov. Jr.*

REPORT OF THE ACTING-COMMITTEE OF PHYSICIANS AND SURGEONS OF THE IRISH DISPENSARIES AND FEVER HOSPITALS.

The session of parliament having closed, and the Medical Charities' Bill, as far as it relates to dispensaries, having become the law of the land, the acting-committee are of opinion that the proper time has arrived for circulating a report of their proceedings. Immediately after their appointment by the general meeting in January last, they at once engaged in, and have since incessantly pursued, every measure which appeared calculated to advance the early enactment of the Medical Charities' Bill, with such amendments as were likely to conduce to its efficiency, and to promote at once the interests of the sick poor and the ratepayers, as well as of the medical attendants of the existing hospitals and dispensaries, and the medical profession at large. The boon conferred by it on the indigent is obvious; and we have no hesitation in expressing the belief that, if carried out in a liberal, and consequently effective manner, it will prove equally advantageous to the community at large, not only by providing them with competent medical and surgical advice in each district, but also, in a merely economical point of view, as the most effective barrier against destitution and a consequent increase of the poor-rates.

Another object kept prominently in view has been to oppose, as far as possible, every projected alteration in the bill tending to interfere with its utility, or the just claims of the medical profession. Amongst the alterations successfully opposed may be specified the attempt, in the first instance, made to render the licence of the Apothecaries' Company a legal qualification under the bill for an appointment to a medical charity; and when this was abandoned as hopeless, a further attempt to carry an amendment, rendering it imperative that no surgeon should be eligible to take charge of a dispensary or hospital without the additional qualification of an apothecary's licence. The absurdity of this proposal is obvious, as it would have gone to disqualify the great majority of the fellows and licentiates of all the colleges of surgeons in the empire from holding office in a medical charity, although fully competent for every medical appointment in the army, navy, and East India Company. The question of qualification has, therefore, been judiciously left to the determination of the commissioners.

Amongst various amendments, successfully advocated by the committee, may be enumerated the transfer of the right of electing the medical attendants of dispensaries from the boards of guardians to the local managing committees—an alteration which, we believe, has received the unanimous approval of the existing governors of these institutions. Another important amendment, which appears due to the declared opinions of the medical profession, was the expulsion of a clause contained in the bill, as originally drafted, rendering compulsory the attendance of all salaried medical officers at coroners' inquests to give professional evidence without any remuneration.

The committee, anxious to guard against the possibility of any local bias, further felt it their duty to exert their utmost influence against a notice of amendment to transfer the right of fixing the salaries from the central board to the boards of guardians; but although they have not succeeded in this to the full extent, their object has been substantially obtained by the insertion of a clause in the eighth section of the act, fully empowering the commissioners, from time to time, not only to *determine the number of medical attendants necessary for any district, but also regulate the amount of the salaries, as well as the time and mode of payment;* thus constituting a court of appeal, with ample powers to investigate and redress any case of hardship that may be brought to their notice.

It is also important to know, that the commissioners take under the bill full powers for altering, if necessary, the dispensary districts formed by the boards of guardians, as well as the exclusive right of framing all the general rules and regulations for the government of these institutions. And this complete controlling power of the commissioners which pervades the bill is of the more consequence, because provision is made for adding to their number a Medical Commissioner, coördinate in power and authority with the other commissioners, and for the appointment of an adequate number of inspectors, who must also be members of the medical profession, thus constituting together a staff, not only fully competent, both by previous experience and peculiar professional knowledge to decide on and fairly appreciate the necessary duties to be performed by the medical officers, but what is of equal importance, armed with full powers to carry out the provisions of the new law.

When it is further remembered that the vexatious uncertainty of the last fifteen years is now terminated, and a certain and equitable mode of supporting the dispensaries substituted for one unjust in principle, and every day becoming more precarious, the committee are of opinion that they have just grounds for congratulating their professional brethren on the Medical Charities' Bill having at last become the law of the land. The only remaining section of the act which it is necessary specifically to allude to, is that which provides for the rights of the present medical officers. The most earnest attempts of the committee were made to have it rendered more stringent and precise; however, as they have good grounds for believing that it will be acted on by the commissioners in a liberal and considerate spirit, they rely implicitly on them for carrying out, in accordance with the ninth resolution adopted at our general meeting, the suggestions which it was not considered expedient to insert in express terms in the bill, and that thus all individual cases of hardship shall be, as far as possible, avoided.

Turning from the subject of the dispensaries, the committee have to express their deep regret, that, owing to a persevering, and in their opinion, a very imprudent opposition, which they do not think it necessary at present more particularly to allude to, the only alternative left to Sir William Somerville was either to relinquish for the present that part of the bill which would have provided for the poor *a sufficient amount and a fair distribution of hospital relief;* or, owing to the advanced period of the session, to see the entire measure fall to the ground. The opposition which rendered this result necessary is the more to be deprecated, as an amendment moved at any earlier period by Sir Robert Ferguson for the exclusion of the hospitals was strenuously opposed by Sir William Somerville, and defeated in the Committee of the House of Commons by a majority of more than three to one—only twenty of the Irish members having voted in favour of it. In the difficult position in which the Chief Secretary for Ireland was then placed, the committee are of opinion that he exercised a sound discretion in passing one moiety of the bill, and they repose the fullest confidence in the intention which he announced in parliament of completing the legislation on the subject, by bringing forward, in the ensuing session, a bill which will at once *relieve the ratepayer from an unfair taxation,* and *provide for the sick poor a sufficient and fairly distributed amount of hospital relief.* They, therefore, feel, that in unanimously passing a vote of thanks to the right honourable gentleman at their last meeting, they were only paying him an imperfect but well-deserved tribute for his zeal and perseverance in endeavouring to pass the bill in its integrity, as well as for his courteous attention to all reasonable suggestions made for its improvement, and for his general support of the honour and interests of the medical profession. The committee, at the same time, felt happy in having an opportunity of expressing their acknowledgment of the services of such members of parliament as zealously supported the bill.

The committee further tendered their best thanks to the Council of the Royal College of Surgeons in Ireland for their earnest and general support of the measure, and especially for their ready compliance, on several occasions, with their request, in sending over to London Dr. Maunsell, the efficient Secretary to the Council, whose very

prompt and valuable services, as reported to us by our secretary, in promoting the objects we had in view, are well deserving of the most grateful acknowledgments of the profession; and, finally, the committee tendered their best thanks to Dr. Knox for his energetic and unremitting exertions to promote the interests entrusted to his care, both as their honorary secretary and as their accredited agent in London, whither he proceeded, at their unanimous request, as soon as it appeared that his presence was desirable, and where he remained, at every inconvenience, as long as the committee considered his services necessary.

The committee having witnessed the success of the measure, towards which their unceasing exertions have been directed, as far as it relates to the dispensaries, feel that the common object for which the profession combined will not have been attained until the hospitals, now in a very precarious position, shall also have been the subject of satisfactory legislation. And as unanimity of purpose is indispensable to any beneficial results, they think themselves called on to express the opinion, that the hospital physicians having made common cause with and assisted, as far as in their power, their dispensary brethren in securing their objects, the latter are bound in honour to support them in return in their efforts to have the hospitals placed in an equally satisfactory position. Even if this were not a sufficient motive for continued and combined exertion, it is scarcely necessary to remind the medical attendants of the dispensaries how deeply their interests are *still* involved in the mode of bringing the bill, already passed, into practical operation, *especially with reference to the re-arrangement of the districts, the regulation of the salaries, and the framing of those general rules by which the amount and nature of the duties to be performed will be accurately defined.*

The committee have every confidence that all fair and reasonable claims on the part of the medical profession, if brought forward and explained in that temperate and conciliating manner which they fully anticipate, and which they take the liberty of earnestly recommending, will receive a favourable consideration on the part of the boards of guardians, in the first instance, and subsequently of the central commissioners, and that the law will consequently be carried out with that willingness which shall ensure its success, in providing certain and efficient medical relief for all classes of the community who have any reasonable claim for obtaining it at the public expense. With these two leading and important objects in view,—viz., the promotion of the effective and satisfactory working of the dispensary law just passed, and the enactment of an equally efficient and equitable hospital amendment bill, the committee, if duly supported by such of their brethren as are interested in the matter, are willing for some time longer to continue their best exertions, in which they have been assisted, on many occasions, by the county secretaries, to whose valuable suggestions on various points they have given all due consideration, and whose services they feel happy to acknowledge; and although the duties which they undertook have at times proved very laborious, especially on the part of the chairman, treasurer, and secretary, they feel amply repaid in contributing, in any degree, to the final adjustment of questions of such importance, not only to their own profession, but to the community at large.—Signed on behalf of the Meeting of Committee,

WILLIAM KINGSLEY, M.D., Chairman.
ALEXANDER KNOX, M.D., Secretary.
J. MORRISON, M.D., Treasurer.

OLIVE OIL IN INTERNAL STRANGULATION.—M. Delotz mentions in the *Revue Medico-Chirurgicale* two cases of intestinal obstruction, in both of which stercoraceous vomiting had ensued. In the first case the patient appeared in an absolutely hopeless condition, when M. Delotz induced him to swallow two pints of olive oil in two successive draughts. To his great surprise the bowels acted a few hours after, and the man recovered. The second case was apparently one of simple constipation, not depending on mechanical obstruction.

STUDENTS' NUMBER OF THE MEDICAL PRESS.

THE STUDENTS' NUMBER will be published on WEDNESDAY, the 29th of OCTOBER. Regulations of Universities, Colleges, and other Institutions for Medical and Surgical Education, properly authenticated, should be transmitted to our Office *without delay*, in order to secure a proper and careful analysis of them. Advertisements of Lectures and Hospitals, Books, Surgical Instruments, and Medicines, should be forwarded in sufficient time to secure a proper arrangement of them.

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, OCTOBER 8, 1851.

THE MEDICAL COMMISSIONER.

THIS functionary may probably take his seat at the Poor-law Board before this reaches our readers; or if not, the next *Gazette* must relieve us from suspense. At the moment we write, we regret to find that, notwithstanding the removal of formidable obstacles, any hesitation exists as to the selection, narrowed as the choice now obviously is. All along we have refrained from making any suggestion respecting the claims of candidates, lest we should be considered advocates of any one of them; restricting our efforts to the achievement of the more important result, the welfare of the medical profession in this country. We have not objected to this man or favoured that; we have simply, in intelligible language, remonstrated against any proceeding which might place an unworthy or incompetent person in such a position. We have asked for a man of *respectable* character to fill the office, and prayed that in professional rank he should be the equal at least of those over whom he is to exercise authority. This surely is not too much to seek for; seeing that without such qualification the confidence and cordial coöperation of our body never can be secured. We are not very strenuous advocates for an undue exercise of patronage in favour of what is called "gentility" in Ireland; neither are we tinctured with any prejudice against men who have risen by their own exertions, but we have an instinctive dislike of meanness of character, and despise heartily those who are indebted to questionable practices for their elevation; above all things, holding in contempt impostors who assume the mask of politics to achieve their objects, and who rely on base services for promotion. Honest political partizans we have no fear of, be their views what they may; such men go wrong sometimes, or perhaps often, but not always, as does the political trader, who can do nothing without "agitation" or intrigue. Then we ask, too, that the person placed in authority over the physicians and surgeons of Ireland shall be a physician or surgeon by education and practice; rejecting with scorn the assumption that the possession of a parchment diploma is to be accepted as evidence of medical or surgical character. The act distinctly provides that the Commissioner shall be "*a physician or surgeon of not less than ten years' standing*," and to that provision they who make this appointment are bound to adhere; not interpreting it according to the mere letter, but honestly adopting its obvious spirit and true object. A physician or surgeon of ten years' standing clearly means a true physician or surgeon, who has been practising medicine or surgery for ten years; a physician or surgeon who has acquired by experience an adequate knowledge of the duties, habits, and feelings of physicians and surgeons.

The act, however, does not, in words, provide that the Commissioner shall be a man of high mind and acknowledged integrity, with a proper sense of justice and impartiality to govern his conduct; that has been provided for by a reliance on the discrimination and regard for high moral qualities possessed by the Minister who makes the appointment. On him devolves the duty of executing this implied provision, and for its effectual execution he must be held responsible. If it should so happen that his choice becomes limited to a selection of one of but two candidates, he will surely name the most worthy, regardless of less imperative obligations. To prefer a pettifogger or a trickster, of confused mind and feeble understanding, to a straightforward man of adequate intellect and ability, would be a downright breach of trust. We argue, however, as if we had some misgivings as to the course about to be pursued, but we really see no reason for apprehension respecting this matter beyond common rumour, and the feverish anxiety universally displayed to see it set at rest. We have no hesitation in stating, that if ever the members of our profession were unanimous, it is now, in the firm resolution to accept the practical interpretation of this act as evidence of the intentions of persons in power respecting them. Upon this, our belief is, will depend the success or failure of the measure.

SURGICAL EDUCATION.

"October comes but once a year, and when it comes it brings," if not "good cheer," at least good advice respecting the means of obtaining it. As surely as Michaelmas geese fly to London, so surely do the journals abound with sage opinions as to the best method of providing for them. In other words, the period of resumption of surgical study naturally enough suggests discussion respecting the methods of conducting it. Matter-of-fact friends may in their simplicity ask, however, what Michaelmas geese have to do with such an inquiry, and it is only right to inform them, that so our unfledged brethren are facetiously designated in the London market, and so do such prolusions as the following preface directions respecting the "cramming" or "stuffing" of them:—

> The evil of "grinding" has been long known to exist, but the extent to which it is actually carried is probably not known to any one board of examiners. Let a man be ever so industrious, let him attend lectures and hospital practice with exemplary assiduity, and have a mind well stored with professional knowledge, still, as a rule, he dreads to encounter hall, college, or university, unless he has undergone that preliminary "stuffing" which the regular routine of hall, college, and university questions has rendered absolutely necessary. . . . . What is the cause of this evil, and what is the remedy? We agree with a correspondent in thinking that the principal cause is to be found in the fact that all men, however learned or experienced, have their crotchets in scientific matters, and these crotchets *will* protrude themselves when their owners are called upon to test the knowledge of junior candidates. Our boards of examiners, if we except that of the Royal College of Physicians which annually undergoes a partial change, are permanent. In the course of time, an examiner thus occupying a permanent office must make known his opinions and peculiar views; he may be effectually gauged by sharp-witted men, both as to the nature of his questions and the answers which will be most satisfactory to him. It was remarked of the late Professor Daniell, when Examiner of the University of London, that although nominally instituting an examination in chemistry, his questions always bore on chemical philosophy, and the voltaic pile. In consequence of this there was a very great demand for his book just before the examinations took place. The same principle holds in other cases; and one unfortunate result of this system is, that the anatomy, physiology, botany, medicine, and chemistry taught in the schools, are measured and valued only as they meet the requirements or the peculiar views of the members of our examining boards. The object of the student is to pass his examination: he cannot do this without looking to the peculiar views of his examiners. Thus, then, the mode of teaching must bend to the style of examinations for the time being, or the anxious student has no other alternative than to resort to the grinder. There must be something defective in a system which leads to such results; for professors of the branches of medical science, who do not occupy examinerships, cannot be expected to surrender their independent views, which, in some instances, may be based on sound experience and observation, to doctrines probably in some cases derived from reading, or second-hand information. We do not say that it is necessarily so, but it by no means follows that because a man, through talent, accident, or good fortune, occupies an examinership, he is thenceforth to be regarded as an absolute oracle in the science in which he professes to examine, and to control the opinions of others who may have been engaged for an equally long, or even longer, period in the practical study of the subject.—*Med. Gaz.*

Of the "evil of *grinding*" we are quite as well aware as our contemporary, but out of this evil may perhaps be extracted good. We denounce the thing, and pray for its total eradication, not recollecting that we may be decrying its use because of its abuse. "*Grinding*" is an evil, a deplorable and a disgraceful one, when substituted, as it undoubtedly is, by some, for every other method of instruction; but honest, judicious examinations, conducted with a view to the student's progressive instruction, as well as the creditable demonstration of his abilities at an examination, is a very different affair. From time immemorial instruction by question has been adopted in elementary schools and universities, while in the schools of medicine and surgery it has been neglected, if not proscribed, until absolute necessity created the contraband trade now complained of. One solitary examination after four years study, is all the surgical colleges provide, and is it any wonder that the student calls for more. In the College of Surgeons of Ireland some years ago an attempt was made to correct this evil, but it was defeated, openly and contumaciously defeated, because it threatened to subvert the system upon which this same "grinding" is founded. At the moment we write attempts are being made to diminish this evil, and if rumour tells truth the attempt has raised a storm of clamour and threat in which revelations of a most startling character get wind. Not merely revelations as to the effect of the illegitimate mingling of the "grinding" and "certificate" system, but of ominous coalitions little calculated to uphold the fair fame of Dublin. These rumours we assume to be exaggerations, convinced that the leading surgeons of this city will never sanction arrangements which may compromise the character of its educational institutions. Great sacrifices have been made to place the Court of Examiners of the College above all suspicion; teachers have been rendered ineligible for the duty, lest a leaning to their pupils should sway their decisions, and stringent oaths, tests, and pledges have been prescribed. Any proceeding, therefore, which threatens to cause a whisper of suspicion as to the possibility of complicated combinations influencing any member of such a body must be jealously scrutinized; and therefore do we venture on these illustrations of the text which suggests our observations. "Grinding," sordid grinding, grinding above all, substituted for the anatomical lectures and demonstrations which the regulations of colleges contemplate, we denounce; but honest legitimate examination, auxiliary to the instruction given in the lecture-rooms and hospitals, we uphold, however such may prove injurious to the pecuniary interests of any individual.

We have not space for comment on another resource in

surgical education, the use of which has also been well nigh forbidden by its abuse. The annexed extract tells of its operation in London. The abuse obviously is the perversion of so valuable and praiseworthy a method to the vile purpose of decoying the student; and strange to say, it is practised more by the Colleges and Universities than by the working Schools. Is it not as clear as the sun at noon day, that certain institutions are openly and unblushingly giving salaries to medical students to sit out lectures, under the flimsy disguise of prizes, "exhibitions," scholarships, and such like dodges. Where is it all to end?

The "prize system" is fraught with much evil, and in many instances is a "mockery, a delusion, and a snare." The object of study is the efficient treatment of disease at the bedside, and this is to be obtained by the strictest attention to what has been called the demonstrative part of teaching. The prizeman in one branch, or even in many, may be really a very ill-educated man, so far as the practice of his profession is concerned; whilst he may for ever have ruined his health by a struggle for foolish distinctions, a certificate, or a medal. The examinations for these "distinctions" are so conducted in our schools of medicine as to afford no kind of test of the practical knowledge of the candidate; and hence a student, with nothing but a retentive memory, may carry off a prize even of the highest kind, and have owed his success, not to any practical knowledge of the subject in which he has been examined, but to a knowledge obtained from books. It is notorious that prizemen generally are not superior practitioners, and they are too frequently liable to the observation of a celebrated divine, regarding a learned but somewhat stupid brother preacher—"Sir, he has so many books upon his head, that they press upon his brain." We may illustrate the evils of the prize system by an instance which some years since came under our notice. The gold medal in the Practice of Physic of one of the largest metropolitan schools, was awarded to a student whose capacity was by no means of a high order, and whose general knowledge was lamentably deficient; he knew little of anatomy and physiology, and was unacquainted with the rudiments of chemistry. He had determined, however, to obtain the gold medal in the Practice of Physic—the highest honour in the school. Accordingly he learned by heart, *verbatim et literatim*, the published lectures of his teacher. When his papers were presented for examination, it was at first supposed that he must have had a book with him in the room appointed for writing the essay; but this was found not to be the case. The medal was awarded to him, and he left the school with a "high honour," but ignorant of every branch of his profession. Let the student, then, not be lured from the legitimate path of study by the geegaws and frivolities of medals and certificates. He has a high, a noble, and a most responsible position to fill amongst his fellow-men; and we warn him against the remorse that may attend the recollection of hours misspent in the acquirement of imaginary distinction, at the expense of those really practical pursuits, the following of which, ardently and consistently, is as essential to his own success and reputation, as it is to the safety and welfare of his patients.—*Lancet.*

TO THE MEDICAL PROFESSION.

JOHN GEORGE BOILEAU AND CO.,

Appeal with confidence to the Medical Profession for support in the undertaking they have so lately commenced. When we began business many of our friends transferred a portion of their orders and some entirely to us, many of whom were connected with public institutions. Now since the recent change with regard to the Medical Charities of this country, of course any public institutions we have supplied must necessarily revert to the contractor for medicines to the Union Workhouse of the district in which each Dispensary is situate. By this alteration we do not lose any amount of business, but merely the pleasure of commercially transacting with those who so kindly patronized us. Many of the Workhouses have lately been open for contract, and indeed unexpectedly we have been declared successful contractors for some of them. The Dispensaries in their district, we presume, we shall have the pleasure of supplying. We use the words "unexpectedly declared successful contractors," for the lists we tendered were priced uniformly low, with a fair remunerative profit attached to each article, and not some few articles priced considerably under cost to catch the eye as a decoy. We thank the Medical Officers who perused our lists, and gave them their favourable consideration and approbation. In addition to our business we have attached a new and voluminous branch—namely, "Druggists' Sundries and Medical Appliances," consisting of Glass Bottles of every size, Glass Measures, Trusses, Pill Boxes, &c , &c., and for these articles we also solicit your orders. We are always supplied not only with the British Chemicals, but also with the German and French of finest description, and shall esteem any commands you may kindly favour us with.

Wholesale Druggists and Manufacturing Chemists,
Importers of German Leeches,
26, MARY'S-ABBEY, DUBLIN.

Sole Wholesale Agents for White's Saccharined Hydrate of Magnesia, In bottles, 1s. *each.*

NOTICE TO THE MEDICAL PROFESSION IN IRELAND.

THOSE Medical Gentlemen who have not yet filled up and returned the Circular for the insertion of their Names, Qualifications, &c., in the forthcoming Medical Directory for Ireland, are requested to do so without further delay, as names cannot be received later than the end of this month. Any gentleman who may not have received a Circular is requested to intimate the same to the Editors, 4, Adam-street, Adelphi, London.

STRAND ROAD DISPENSARY, CORK.

AT a Meeting of the Friends and Subscribers, held on the 18th of September, the following expression of feeling embodied in a letter, signed by five hundred persons of all classes, was handed to the Chairman, and unanimously adopted:—

To the Chairman of the Meeting.

SIR,—We, the undersigned Inhabitants, residing within the district of the Strand Road Dispensary, having learned that an act of parliament has recently passed, and is now about to come into operation in reference to the Dispensaries of Ireland, by reason of which an alteration is likely to be made in the management of those Institutions, avail ourselves of the opportunity of this day's meeting to record the very high opinion we entertain of Dr. Charles Armstrong's skill, kindness, and attention to this important charity. A sense of public duty, as well as a regard for the sick poor, urge us to request that in any alteration which may take place under the new bill, this district will not be deprived of the able, zealous, and indefatigable exertions of Dr. Armstrong, towards whom we believe there exists throughout the district but one feeling, that of high respect and admiration.

[Here follow the signatures.]

September 22, 1851.

BALLIBAY DISPENSARY.

At a numerously attended Meeting of the Subscribers, held in the Market-house, on Tuesday, the 30th of September,

Thomas Lucas, Esq., in the chair,

It was proposed by the Rev. Elias Tardy, Rector of Aghnamullen, seconded by John Oulton, Esq., and carried by acclamation:—That the following Address be presented to Joseph Robinson, Esq., L.R.C.S.I., and L.K.Q.C.P., &c.

ADDRESS.

We, the Subscribers to the Ballibay Dispensary, are desirous of recording, which we do with feelings of the utmost gratification, our testimony to the medical skill and humane manner in which you have discharged the duties of medical officer to this institution for the last five years—years of unexampled severity, when famine, cholera, fever, and other severe diseases were experienced in this unhappy land by all classes under the inscrutable visitation of the Most High.

We cannot let this opportunity pass, as the last we may have as Subscribers to the Dispensary, in consequence of the medical charities being about to come under the poor-law system, without expressing our assurance of the high respect and esteem we personally entertain towards you, and trust that in the alteration which is now about to take place, we shall continue to enjoy your invaluable medical services in this locality.

(Signed) Thomas Lucas, Chairman.
John Dunbar, Secretary.

REPLY.

Gentlemen,—It is with feelings of the utmost gratification that I have read the very complimentary Address which your Secretary has just handed me, and although I fear that those compliments are much overdrawn, I cannot but feel exceedingly gratified that my humble exertions in my professional capacity have met with such warm approbation from you. Even when I look back upon the disease and suffering I have been witness to, and think of the labour I have undergone while Medical Attendant of your Dispensary, I feel that your eulogiums have amply compensated me for both.

As the connexion between us is, I am sorry to say, soon to terminate, I beg to return you my most sincere thanks for the support and good feeling you have always evinced towards me, and throughout life will ever bear in grateful remembrance the kindness I have experienced in the outset of my profession from you and the inhabitants of this neighbourhood.—Your obliged servant,

Joseph Robinson.

To the Subscribers to Ballibay Dispensary.

MOUNTRATH DISPENSARY.

At a General Meeting of the Subscribers to the Mountrath Dispensary, held on Tuesday, the 30th of September,

The Very Rev. the Dean of Clonfert in the chair,

The following Resolutions were proposed and unanimously agreed to:—

"That on the act of parliament for the regulation of Dispensaries coming into operation on the 1st day of October, and as under the provisions of that act, the Subscribers will then have to surrender the management of the Mountrath Dispensary to the Poor-law Guardians, we feel it a duty that we owe to Dr. Smith, to express in the strongest manner our sense, not only of his high qualifications, but also of his laborious exertions in behalf of the sick poor of this extensive district, and of the unremitting care and attention which he bestowed upon them; and while we would thus convey to Dr. Smith our unanimous approval of his skill and care, we desire, at the same time, to record an expression of the pleasure with which we look forward to his continued connexion with this district, and the gratification which we have in thinking that our poor shall still be permitted, under other management, to have the benefit of his valuable services."

"That we consider the establishment of District Hospitals, as contemplated under the Medical Bill introduced by Sir William Somerville last session of parliament, is calculated to afford a greater facility of administering a prompt and extended system of relief to the poor than there now exists, and that while we confidently look forward to his renewing his exertions in the ensuing session of parliament to complete a measure for the establishment of these hospitals, we give him our best thanks for his able and efficient advocacy of a permanent and effective system of relief for the sick poor of this country."

Just published, 8vo, price 7*s.* 6*d.*, cloth,

PATHOLOGICAL AND PRACTICAL OBSERVATIONS ON STRICTURES, AND SOME OTHER DISEASES OF THE URINARY ORGANS.

By Francis Rynd, Esq., A.M., M.R.I.A.,
Fellow and Member of Council of the Royal College of Surgeons in Ireland;
Surgeon to the Meath Hospital and County Dublin Infirmary;
Her Majesty's Medical Superintendent of Convicts in Ireland;
Member of the Royal Medical Society of Edinburgh, of the Pathological Society of Edinburgh, of the Pathological Society, &c. &c.

"In this treatise the causes, nature, and symptoms of stricture are explained; and its consequences, including disease of the bladder, retention of urine, and abscesses in the perinæum, described. The treatment, both local and constitutional, is laid down; and the management of the catheter and bougie fully detailed. Disease of the prostate gland is also investigated, and its treatment considered. It contains in brief space, and at a moderate price, much valuable and instructive matter touching a subject which no surgeon can overlook. To us it appears a useful addition to our stock of information on this subject, and creditable to Irish surgery."—*Medical Press.*

"No volume was ever more correctly named according to its contents than that which is now before us, the diseases of which it treats are described from nature, the views which it propounds are based on pathological science, and the treatment recommended is derived from an extensive practical acquaintance with the almost endless forms under which diseases of the urinary organs present themselves to the surgeon. We know of no work that presents such comprehensive or such admirable rules on the subject of treatment."—*London Medical Gazette.*

"The book is very carefully written, and may be consulted with advantage by those who are desirous of refreshing their knowledge, as also by the student."—*London Journal of Medicine.*

"The subject of fistula in perineo and its complications are treated of in this book in a remarkably clear and judicious manner. The remarks, &c., may be read with profit by all reflecting surgeons. It is, without doubt, an able and thoughtful production, and has our cordial recommendation as one of the best of the modern contributions to this branch of surgery."—*British and Foreign Medico-Chirurgical Review.*

"There is much that is good, both as regards the matter contained, and the manner in which the work is written. The remarks upon forcibly penetrating an impermeable stricture in retention, are excellent. There is much sound and valuable matter in this book."—*Lancet.*

"The practical precepts with which it is replete will amply remunerate the reader for the time expended in its study. We again repeat it as our deliberate opinion that these 'Pathological and Practical Observations on Stricture' reflect great credit upon the Author."—*Dublin Quarterly Journal of Medical Science.*

"We have been much pleased with the perusal of this work; it is full of sound practical research, and contains much that will prove valuable to the surgeon." *Medical Times.*

"It is eminently practical, which is the highest praise that, in my opinion, can be given to a surgical essay."—*Sir Philip Crampton's Letter to the Author.*

"Your book is an important addition to the series of Meath Hospital Works."—*Dr. Stokes's Letter to the Author.*

C—Incumbered Estates Commission Offices.
D—General Engineering, Geological Survey, and Valuation Office.

GENERAL ENGINEERING, GEOLOGICAL SURVEY, AND VALUATION OFFICE,
1, HENRIETTA-STREET, DUBLIN,

JOHN IRWINE WHITTY, A.M., LL.B.,
Member of the Geological Society, Civil Engineer and Valuator,
DIRECTOR.

DRAINAGE, AGRICULTURAL IMPROVEMENTS, ETC.

Plans and Estimates made, and Work superintended.

The General Engineering, Geological Survey, and Valuation Office continues to afford most ample facilities to Landed Proprietors desirous to advance the agricultural and other improvement of their estates—Drainage, the Analysis of Soils, Surveying and Valuation of Property, the furnishing Reports on the Geology of Localities supposed to contain Minerals, and the Working of Mines, being undertaken and conducted to the greatest advantage, as regards excellence of design and execution, and economy in the expenditure of capital, such as can only be ensured by much professional experience, and a thorough acquaintance with the efficient management of workmen.

Mr. Whitty's services may be engaged in any part of the kingdom, at a fixed charge for his time, together with moderate travelling expenses.

INCUMBERED ESTATES—RENTALS, SURVEYS, VALUATIONS, ETC.

The above Office affords peculiar advantages to Solicitors for Printing of Rentals, Publishing of Notices, &c.

Mr. Whitty begs leave to announce that, in connexion with Surveying, Mapping, and Valuation of Property, and Lithographing of Plans and Perspective Views, which he extensively and with the greatest success carries on for the Incumbered Estates Court, he also undertakes the Printing of Rentals, and Publishing of all requisite Notices connected therewith.

Parties who employ him for Printing their Rentals have been relieved from all anxiety as to the correctness of the calculations and tots, and the appropriate disposition of the matter.

Mr. Whitty procures (at a charge sanctioned by the Court) the Government and Poor-law Valuations of any named property. Information on this head, supplied by Mr. Whitty, may be relied on as correct, he being an Attested Valuator under the Poor-law Commissioners, and thoroughly acquainted with the legitimate mode of using the Ordnance Maps and applotting Mr. Griffith's Townland, so as to render it a Tenement Valuation.

All commands are punctually attended to at the
OFFICE, 1, HENRIETTA-STREET,
where Specimens can be seen of Rentals, Maps, &c., and much useful information obtained.

N.B.—Mr. Whitty would take charge of another Apprentice. He was himself instructed under Sir John Macneill and other eminent Professors in their respective sciences; and having, to the satisfaction of all parties, completed the Drainage of St. Stephen's Green and many other Public Contracts, has obtained numerous creditable Testimonials, a printed copy of which can be forwarded by letter when required.

ROYAL COLLEGE OF SURGEONS.

SCHOOL OF SURGERY.

THE Session 1851–2 will not commence until the 27th of October. Gentlemen, however, residing in Dublin can commence their Dissections immediately on entering their names for the ensuing Winter Course of Practical Anatomy.

THE ROYAL MEDICAL HALL,
64, DAME-STREET, DUBLIN.
☞ *Change of Proprietorship.*
BEWLEY, OWEN, AND CO., APOTHECARIES,
(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of
THE ROYAL MEDICAL HALL,
beg particularly to state, that henceforth
THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS,
will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,
BEWLEY, OWEN, AND CO.'S ESTABLISHMENT
embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick-room and nursery.

*** GENUINE COD-LIVER OIL,
of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

DISPENSING OF MEDICINE.

G. OLDHAM AND CO.,
PHARMACEUTICAL CHEMISTS AND APOTHECARIES,
From BEWLEY and EVANS',
No. 107, GRAFTON-STREET, DUBLIN,
(Corner of Suffolk-street,)

BEG to return their grateful acknowledgments to the Medical Profession for the support they have hitherto received, and which they will regard as a fresh motive for exertion. Abstaining altogether from visiting as Apothecaries, except for the application of Leeches, Cupping, and such operations as are performed under medical advice, they will continue to devote themselves exclusively to the duties devolving on the pure Pharmacien.

Having had much experience in Practical Pharmacy, and being resolved to spare neither trouble nor expense in order to have every article of superior quality, they hope by attention, "carefulness," punctuality, and moderation of charges, to commend themselves to the approbation of those who may entrust them with their commands.

☞ *G. O. and Co. invite attention to their present stock of Surgical Instruments, all of which are manufactured on the most modern and improved principles.*

CITY OF DUBLIN HOSPITAL.

THE Winter Course of Practical, Medical, and Surgical Instruction will commence on the 27th of October.

The Clinical Lectures will be delivered by Dr. Jacob, Dr. Benson, Dr. Beatty, Mr. Hargrave, Mr. Williams, Dr. Geoghegan, and Mr. Tufnell.

Dr. Jacob will deliver a full Course of Lectures on Diseases of the Eye; Dr. Beatty, select Lectures on Diseases peculiar to Women and Children; and Mr. Tufnell on Military Surgery.

Sir Henry Marsh, Sir Philip Crampton, Professor Apjohn, Professor Porter, and Mr. Cusack, give their assistance in cases requiring consultation.

Certificates of attendance are received as qualification by all the Colleges, Halls, and Boards.

DISEASES OF THE EYE.

DR. JACOB will deliver a full Course of Lectures on the Anatomy, Physiology, and Optical Mechanism of the Eye, during the ensuing Session, in the College of Surgeons, and also a separate Course on its Pathology and Diseases, with the Operations required in their Treatment, in the City of Dublin Hospital.

MEDICAL SCHOOL.

ANDERSON'S UNIVERSITY, GLASGOW.

THE Winter Session will begin on Tuesday, November 4, 1851. Lectures will be delivered daily for six months on the following branches of medical science:—

Anatomy, Descriptive and Physiological—Dr. M. S. Buchanan.
Anatomy, Demonstrative and Surgical—Dr. M. S. Buchanan.
(Demonstrator—Dr. George Buchanan.)
Principles and Practice of Surgery—Dr. Hunter.
Principles and Practice of Medicine—Dr A. Anderson.
Institutes of Medicine—Dr. Eben. Watson.
Materia Medica, Pharmacy, and Dietetics—Dr. Easton.
Chemistry—Dr. Penny.
Practical Chemistry—Dr. Penny.
Midwifery and Diseases of Women and Children—Dr. Paterson.
Medical Jurisprudence and Police—Dr. Crawford.
Natural Philosophy (three times a week)—Dr. Taylor.
Mathematics—Mr. Laing.

Summer Courses of Anatomy, Midwifery, Chemistry, Materia Medica, and Botany, begin in May.

Botany—Mr. Bell.
Fee for each Class, £2 2s.

Classes for French, Drawing, and German are also taught in the University.

Certificates of attendance on the above courses are received by the Universities of Oxford, Cambridge, London, Aberdeen, and St. Andrew's; by all the Royal Colleges of Surgeons in Great Britain and Ireland; by the Faculty of Physicians and Surgeons in Glasgow; and by the Army, Navy, and East India Boards; and the Apothecaries' Company.

Students attending the Medical Classes have the opportunity of witnessing the practice of the following hospitals:—viz., Lying-in Hospital, 10s. 6d. for six months; Eye Infirmary, £2 2s. for six months; Royal Infirmary, £8 8s. for two years, including Medical and Surgical Clinical Lectures, which are delivered four times weekly. The patients admitted to the Eye Infirmary average 900 annually; those admitted to the Royal Infirmary, nearly 3000; besides 6000 out-patients, treated at the Dispensary. Average number of surgical operations 120 annually.

The Dissecting-room is free to those attending either of the above Courses of Anatomy, and attached to it there have been opened a Reading-room and Museum for the use of the Anatomical Students.

The new and extensive Laboratory of the Institution, fitted up expressly for gentlemen desirous of pursuing Practical and Analytical Chemistry, is open daily from eleven till four o'clock. No charge for apparatus and materials in the class for Practical Medical Chemistry.

The University Museum, a splendid collection of specimens of Natural History, including more particularly those of Zoology, Mineralogy, and Antiquities, is open to all Students attending the University.

A valuable Medical Library is also attached to the Medical School.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

SCHOOL OF SURGERY.

THE Winter Session, 1851–52, will commence on Monday, October 27.

Anatomy and Physiology—Dr. Jacob.
Descriptive Anatomy—Dr. Hart and Dr. Macdonnell.
Surgery—Mr. Porter and Mr. Hargrave.
Practice of Medicine—Dr. Benson.
Chemistry—Dr. Barker.
Midwifery—Dr. Beatty.
Comparative Anatomy—Dr. Jacob.
Dissections by the Professors of Anatomy and the Demonstrators—Dr. Leeson, Mr. Labatt, Mr. T. D. Hargrave, Mr. Malcolmson, and Mr. Morgan.

THE SUMMER SESSION WILL COMMENCE THE 3RD OF MAY.

Materia Medica—Mr. Williams.
Botany—Dr. A. Mitchell.
Medical Jurisprudence—Dr. Geoghegan.
Practical Chemistry—Dr. Barker.
The Fee for each of the above Courses is Two Guineas.

For further information apply to any of the Professors, or to the Registrar. By order,

W. BOYLAN, Registrar.

MEATH HOSPITAL AND COUNTY OF DUBLIN INFIRMARY.

THE Winter Session commenced on the 1st of October. The usual courses of Clinical Instruction will commence on the first Monday in November, and will be continued through the session by the Physicians and Surgeons of the Institution.

Arrangements have been made to prevent the hours of attendance and lectures from interfering with any other place of instruction in Dublin.

The Medical and Surgical Clinical Instruction will be carried on on the alternate days—Mondays, Wednesdays, and Fridays for SURGICAL; and Tuesdays, Thursdays, and Saturdays for MEDICAL Instruction.

Operations, unless in cases of emergency, will only be performed on the days of Surgical Instruction.

A Surgical Registry of all cases admitted into the hospital is carefully preserved, and is open to the inspection of the pupils. A dispensary is attached to the hospital, in which the pupils are allowed to perform all the minor operations in Surgery, under the guidance of the attending Surgeons. From 200 to 300 patients are prescribed for and relieved in the dispensary daily.

The following premiums are to be awarded, as usual, at the close of the session:—

1. The Clinical Medical Premiums.
2. The Clinical Surgical Premiums.
3. The Stethoscope Prizes.

Of these there are two in each class to be awarded according to the order of merit.

The situation of Resident Pupil is open to pupils as well as apprentices of the hospital.

Special recommendatory certificates are given to such gentlemen as have filled the situation of Clinical Practising Assistants in the hospital for at least four months to the satisfaction of the medical officers.

Certificates of attendance on this hospital are acknowledged all over the empire.

The hospital is only a few minutes walk from the College of Surgeons.

The Medical Clinical Instruction is given by Dr. Stokes, Regius Professor of the Theory and Practice of Physic, Trinity College, Dublin, &c.; and Dr. Lees, Fellow of the College of Physicians, Lecturer on the Practice of Physic, Examiner in Medicine to the Queen's University in Ireland, &c.

The Surgical by Sir P. Crampton; Mr. G. Porter, A.M., F.R.C.S.I., &c.; Mr. Porter, A.M., Professor of Surgery, Royal College of Surgeons, &c.; Mr. Collis, A.M., F.R.C.S.I.; Mr. Smyly, A.M., F.R.C.S.I., &c.; and Mr. Rynd, A.M., F.R.C.S.I., &c. &c.

A Course of Lectures on Operative Surgery will be delivered in the course of the Sessions by Sir Philip Crampton.

For further particulars apply to Francis Rynd, Esq., Secretary, No. 19, Ely-place, or at the Hospital.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin.
Wednesday, October 8, 1851.

CASES IN SURGERY.

GUNSHOT WOUND IN LEFT AXILLA.

LIGATURE OF LEFT SUBCLAVIAN AND SUBSEQUENT LIGATURES OF BRACHIAL AND SUBSCAPULAR ARTERIES.

By John Watson, M.D., Surgeon to New York Hospital.

On November 25, 1850, Post Van Pelt of Paterson, New Jersey, boy, aged 14, of good constitution, was accidentally shot in the left axilla. The shot, to the number of twelve or fifteen, entered the axilla nearly at a right angle with the trunk of the body, and separately made but little external laceration. I first saw the patient three-quarters of an hour after the receipt of injury. There had been profuse arterial hæmorrhage which had ceased spontaneously.

Appearance of patient.—Skin cold, pale, and shrunken; pulse in sound extremity feeble and intermitting, and no perceptible pulse in injured arm. Cold applications and an anodyne at night. 26th. Patient has passed a comfortable night; pulse in the sound arm 120, and if not deceived by the pulsation of my own fingers, I detect a slight pulsation at the wrist of the injured extremity; the whole shoulder, arm, and vicinity of wound are much swollen. Cold dressings continued. 28th. Pulse 100; pulsation in the injured arm increasing slightly in regularity and fulness; and the swelling has somewhat subsided; the patient complains of no pain. Continue cold dressings. 29th. Much about the same; bowels opened by enema.

Dec. 3rd. Patient improving; the swelling has nearly subsided; the wound is suppurating; the pulse on sound side soft, and beats at 110; circulation in injured extremity becoming more regular each day; the patient complains of pain in hand and forearm. Ordered poultice of linseed meal to wound. 4th. Having left patient's house but a few steps, I was called back, and found considerable arterial hæmorrhage, which was controlled at once by pressure over the subclavian artery. During the next thirty-six hours, the hæmorrhage recurred five or six times, some four or five pints of blood being lost, which hæmorrhages always yielded to compression on subclavian artery. Cold dressings ordered to be reapplied. 5th. Pulse on the sound arm 120, and hard, and faint pulsation in the injured arm; I noticed a small tumour forming in axilla of injured side, which proved to be a false aneurism; tumour increasing rapidly, by night being as large as a goose's egg. On consultation, it was decided to ligature the subclavian artery. 6th. Having requested the aid of Dr. Watson, he proceeded to ligature the subclavian artery beyond the scaleni, while the patient was under the influence of ether. At this time the pulse at the wrist was imperceptible, but the aneurismal swelling in the axilla beat strongly. The steps of the operation need not be detailed further than to say that, before securing the subclavian, the external jugular vein, and a small ascending vessel, probably a branch from the acromial artery, required the application of a ligature, and that very little blood was lost. I visited the patient four hours after the operation, and found the aneurismal tumour and the swelling in the arm sensibly diminished, and no pulsation to be perceived; pulse in sound arm 120; patient in good spirits. 8th. Aneurismal tumour burst and discharged a quantity of coagula and semi-fluid blood.—9th. Removed the outer dressings from wound made in operation; there was some discharge of grumous blood from this, and no indication of union; pulse about 130, and hard, with a jerking feel; bowels moved by enema. 12th. Patient again improving; pulse better; respiration good, and less excitement about the vessels of the neck; there was a venous hæmorrhage to-day from the incision above the clavicle, which ceased spontaneously, and did not return. 15th. Again removed dressings; wound looks healthy; the ligatures on the superficial vessels and the main ligature remain firm; pulse 110, and softer. 18th. Both wounds suppurating finely; strong hopes of patient; four hours after my first visit a profuse hæmorrhage occurred; the flow having ceased, its point of issue could not be ascertained, nor could I decide as to whether it was venous or arterial. 19th. The hæmorrhage again occurred; it was now clearly arterial, and from the original seat of injury in the axilla. It ceased spontaneously. Pulse 120, and jerking. 20th. Dr. Watson, being summoned from New York, arrived just in time to witness a third recur-

rence of the arterial hæmorrhage, which was tremendous. Not being able to control it by pressure, and the case admitting no delay for the administration of ether, he made an incision two and a half inches in length below the clavicle in the course of the subclavian artery, and through the pectoral muscles into cavity made by injury in axilla. The seat of hæmorrhage not being readily discovered, the cavity was stuffed with pieces of sponge, and an incision about three inches long made in arm over brachial artery, which was found open, but flaccid and dry. It was then tied. The sponges were next carefully removed, piece by piece, and we discovered that the repeated hæmorrhages *subsequent* to the ligature of the subclavian were not from the lacerated brachial artery on the distal side, but from the channel of communication between the posterior scapular and subscapular arteries; which latter, with its accompanying nerve, lay gaping and much enlarged at the bottom of the cavity. The subscapular artery, which was still bleeding, was finally secured. The axillary artery was found to have been much disorganized by the original injury. A number of shot, lying loose, were scraped out with the other contents of cavity, which now remained dry. Patient lost by this last hæmorrhage nearly two quarts of blood without inducing syncope. After the operation bandages were placed on the lower extremities, and stimulants administered with the view of supporting the circulation and inducing a vigorous reaction. 21st. Patient gradually sinking; stimulants freely and frequently administered. 22nd. Patient died this morning, having never rallied from the last profuse bleeding. Previous to death the arm showed symptoms of gangrene.

Autopsy.—The post-mortem examination was confined, by request of the friends of the patient, to the incision above the clavicle. The ligature on the subclavian artery was found loose, and the vessel obliterated some distance each way. (The superficial ligatures had come away previously on the 20th.) Union had taken place to a large extent at the seat of the operation, although there was a sinus along the course of the artery, terminating at the original seat of injury in axilla; arm extensively gangrenous.

Remarks.—This case presents analogous features to one of Dr. Mott's, with the exception of the difficulties arising subsequent to the ligature of the subclavian artery—difficulties caused by the enormous sloughing process in the original wound. We would not have been justified in enlarging the wound, and tying both ends of the injured axillary artery, and the result of the case shows that such a procedure would have been of no service. The diagnosis was at first difficult, both as to vessel and extent to which the vessel was injured. Certainly the indications pointed out the axillary artery; but might not the injury of a minor vessel, with the profuse hæmorrhage and shock to the system, have produced the same symptoms? Again, hæmorrhage had ceased upon my seeing patient, and pulse returned in a few hours (but feebly and intermittingly indeed). And would ligatures upon both ends of bleeding vessel have prevented the terrible disorganization of the parts?

It will be perceived that the secondary hæmorrhage prior to the operation took place on the 4th of December, eight days after the receipt of injury; and one day intervened between the first hæmorrhage and the ligature of the subclavian. This delay was unavoidable. It will also be remarked that, during all these repeated bleedings, even up to the last operation, the pulse varied but little; and the patient's strength, courage, and spirits remained good. Both operations were performed under great deficiency of light, so much so that the last required the aid of a candle. The venous hæmorrhage, mentioned as occurring on the 12th, probably arose from the divided end of the external jugular, from loosening of the ligature.

Guthrie says that, "when there is a wounded artery which has been duly secured above and below the wound, or when there is an artery in a state from which it may be feared blood may flow, from any or whatsoever cause, the patient should never be allowed to stir from the recumbent position until the external wound has healed;" a precept which was most religiously observed in this case. The last hæmorrhages were brought on by the slight exertions made in micturating.

The "operation" on the subclavian ought to be considered successful, so far as that vessel was concerned, the patient being carried off by causes not altogether unforeseen, but unavoidable and totally unconnected with the ligaturing of the vessel. Dr. Watson says, "he regrets we did not resort to transfusion of blood immediately after checking the flow at the last operation." It certainly was worthy of trial, but I have some doubts as to the benefits that would have been derived from it; for the circulation having been but feeble in the injured arm from the day of the injury, and that circulation being still further diminished by last operation, leaving only the small acromial and the capillary circulation for the nourishment of the arm, gangrene was to be expected, and it did make its appearance; to check which, had the patient survived, would probably have required amputation at the shoulder joint.—*Amer. Jr.*

INFIRMARY REPORTS.

DENBIGHSHIRE INFIRMARY.

(Cases under the care of Richard Lloyd Williams, M.D.)

TUMOUR OF THE ORBIT.

On the 7th of October, Mary Williams was admitted as an in-patient of the Denbighshire Infirmary. The eyeball protruded extensively, and her sufferings were very great, both on the orbit as well as through the head to the occiput. Her general health was very little impaired. After giving the patient a few days to recover the effects of her journey, and administering to her some house aperient medicine, I had a consultation with my colleagues, and it was agreed that an operation should be attempted for the relief of this formidable disease. I determined to make an incision through the upper eyelid, so as to expose the tumour, and to be guided by appearances. If I found the eyeball involved in the disease, I proposed to remove the whole mass. Chloroform was judiciously administered to the patient by my friend Mr. Turner. Upon making an incision along the whole of the eyelid covering the tumour, and making a careful examination of the parts, I was gratified to find the eyeball totally free from disease. The tumour I found occupied the whole of the orbit, even to its very bottom. It firmly adhered to the eyeball on its lower, and to the orbit on its upper, side. My friend Mr. Chambers steadily held a tenaculum which I had passed through the tumour, and gradually drew it out, whilst I carefully dissected it from its attachments above and below. Notwithstanding the effect of chloroform, there was a good deal of writhing during this process, and the sac was ruptured, and its contents escaped. With the aid of a hook, and a pair of crooked scissors, used for the operation of squinting, I succeeded in clearing away the whole of the adhering sac from the bottom of the orbit. Although there was a good deal of hæmorrhage during the operation, it nearly ceased before I had completed it. The exterior wound was brought together by four or five sutures, and lint dipped in cold water applied. An opiate was given, but immediately rejected. The patient suffered considerable pain in the eyeball and head for eight or ten hours, when she became perfectly easy, and more free from suffering than she had been for months. The external wound healed by the first intention.

I removed the ligature at the end of four or five days, and upon gently raising the eyelid I was gratified to find the eye perfectly healthy, and the vision very slightly impaired, and it gradually recovered so as to be quite as good as that of the other eye before she left the infirmary, which she did at the end of a month from the date of her admission. The only deformity remaining at the time of her discharge was a little falling of the eyelid, produced by the extreme distension and protrusion of the eyeball previous to the operation, and which I am willing to hope

time will remove. I have since heard that all deformity has disappeared, and the patient remains perfectly well.

COMPLICATION OF HERNIA, HYDROCELE, AND SCIRRHOUS TESTICLE.

This case is more remarkable on account of the complication of diseases existing in the same scrotum simultaneously, than from any particular feature in either.

Roger Davies, aged 70, was admitted into the Denbighshire Infirmary, on account of strangulated scrotal hernia, which was reduced by the taxis, with the aid of tobacco injections. After the reduction of the hernia the patient was perfectly free from pain, but the bulk of the scrotum remained very considerable. There was evident fluctuation, and upon introducing a trocar a large quantity of dark-coloured serum was discharged. Notwithstanding the reduction of the hernia and the evacuation of the fluid from the tunica vaginalis, a hard mass still remained, which, upon examination, proved to be a scirrhous testicle. He was a fine old fellow, and upon my observing that his troubles were not at an end, and that his testicle was diseased, he said,—"Then pray take it off and make a good job of me." This was immediately done, and in the course of a few weeks the old man was rewarded for his courage and discharged quite well.

UNUNITED FRACTURE TREATED BY EXCISING THE ENDS OF THE BONES.

Cadwalader Lloyd, admitted Jan. 20. The history he gave was, that he had been thrown from a horse, who had kicked him severely while on the ground, some months previous to his admission. After a trial of pressure, friction of the extremities of the bones, &c., I determined upon cutting down upon the fracture, and sawing off the ends of the bones. A pretty free incision was made in the posterior portion of the arm, so as to avoid the bloodvessels and nerves which traverse the inner part of the humerus. I found the upper portion of the fracture completely embedded in, and firmly adhering to, the fibres of the triceps muscle. The spiral nerve was avoided by a spatula, held so as to keep it out of the way of injury. The inferior portion of the fractured bone was firmly fixed in the body of the biceps muscle. It required much caution to dissect the spiculated portions of the bones from the fibres of muscles to which they firmly adhered. This, however, was accomplished, with the loss of only a few drops of blood. The extremities of the bones were sawn off and the parts brought into complete apposition. Splints were applied.

My patient was allowed to get out of bed and try the strength of the arm towards the end of April, when the bones were found perfectly and firmly united, and he was soon afterwards discharged cured. During the following summer I heard that he could use the arm with as much strength as ever he had done.—*Prov. Jour.*

DISPENSARY REPORTS.

STRAND ROAD DISPENSARY, CORK.

MEDICAL REPORT.

To the Governors and Subscribers.

My Lords and Gentlemen,—Within the past year, there were entered on the books 3866 patients. During spring, fever prevailed throughout the district, particularly in the neighbourhood of the barracks, the general character of which, however, was not severe nor protracted: 75 cases were sent to the fever hospital—a circumstance that tended considerably to check the spread of this annual epidemic. The value of fever hospitals is so paramount that I beg to repeat what I said on this subject in my last report—viz., "310 fever patients were entered on the books, 41 of whom were sent to hospital, and here I cannot dwell too strongly on the prudence of immediately removing to hospital all cases of *contagious* fever, with the view of at once arresting the spread of disease. I met some striking instances, where, from want of early removal, fever spread, not only amongst members of the same family, but extended itself to that of others in the neighbourhood. Fever also not unfrequently finds its way into the houses of the rich from those of the poor, a *fatal* case of which came within my cognizance not long since."

26 cases of midwifery received assistance, some of which were of a *serious* nature.

Several children were vaccinated, particularly within the last two months, as some cases of small-pox have lately made their appearance. In one family, four were attacked by this frightful disease, none of whom had been vaccinated. The disease did not spread, which is attributable to the fact, of all in the neighbourhood having had the cow-pock.

The four children attacked by the small-pox lately came into the district from a distant locality.

The ophthalmic applicants have been increasingly numerous. A species of eye disease, termed "purulent ophthalmia," which, within the last year, has prevailed in some of the union workhouses so alarmingly as to have required the interference of government, has also appeared amongst us; in a few instances, so severely as to have attacked entire families. Without the assistance derived from the dispensary, many of these would have lost their sight. The disease is much mitigated.

A considerable number afflicted with deafness and other affections of the ears have sought relief, many of whom have been permanently cured.

Two remarkable cases of lock-jaw, termed "tetanus," arising from slight wounds, occurred at Hyde Park, in the persons of very fine and intelligent boys (brothers), one 14, the other 12 years old. The latter was not seen till four days after the occurrence of alarming symptoms, which terminated fatally; the latter was seen early and recovered.

At present measles are very prevalent, and though great numbers of children and a few adults have been attacked, the disease hitherto has proved fatal in but few instances.

15 cases of *common* cholera occurred since the commencement of autumn, one of the most severe being a man named Levey, gardener to General Turner, from whose family immediate and kind assistance was throughout administered. All terminated favourably.

I am happy at having so suitable an occasion of expressing my gratitude to the medical gentlemen of the North Infirmary, through whose kindness I was enabled to procure hospital relief for persons who could not be treated as dispensary patients with any reasonable hopes of success. To Dr. Finn I feel greatly indebted. I am also much obliged to Dr. Lloyd of the South Infirmary. To the instrumentality of these hospitals, I can trace the preservation of some useful lives.

The peculiar value which dispensaries possess over all other medical charities consists in paying domiciliary visits, 1360 constituting the average made within the last year.

The district commences at Silver Spring on the east, and extends to Ship-street and Audley-place on the west, including Silver Spring, Ballinamought, Cahirgoll, Mayfield, Ashburton, Glenwood, Barrackton, the three Glanmire Roads, St. Luke's, and Audley-place.

The great amount of labour in connexion with this dispensary arises, in a great measure, from the large population of the district, as well as from the fact, that the medical attendant discharges the duties of *physician, surgeon, accoucheur, and apothecary*, without assistance from *any* source. No doubt, the last census furnishes an alarming decrease in the general population of Ireland; exceptions to this, however, occur in some isolated localities, such as cities, large towns, and their immediate vicinities, into which, from obvious reasons, numbers of persons have flocked. The district of the Strand Road Dispensary forms one exception, for by reference to the police authorities, it is shown that its population now is greater than it was in 1841.

The Medical Charities' Bill being now law for ever severs you from the future management of the dispensary. In taking my leave of you, therefore, I would be insensible to all refined feeling did I not speak most gratefully of the kind consideration I have met from all in discharge of my arduous duties, and in terms of admiration for the sympa-

thy I have seen so continually evinced by many towards the sick poor. The benefits of this dispensary are long since placed beyond dispute. The Roman Catholic clergymen, whose calling brings them in constant connexion with the people, bear ample testimony to this fact. To these gentlemen I feel greatly indebted, not alone for their uniform kindness to me on all occasions, but for the very flattering manner in which they have so frequently spoken of my labours.

I have the honour to remain, my lords and gentlemen, your very obedient servant,

CHARLES ARMSTRONG, M.D., Surgeon.

September 18, 1851.

CASES OF INJURY OF THE HEAD.

By Mr. IKIN of Leeds.

IT has often been stated, when speaking or writing on accidents to the head, and their various symptoms, that discharge of blood from the ears is a symptom that indicates fracture of the base of the cranium. That this is often the case is doubtless correct, but that it is so invariably may be justly questioned.

Case 1.—Mr. R——, aged 25, a healthy, fine young man, was thrown out of his gig by his horse running away and dashing against a heap of stones. He was taken up insensible and carried home. He continued unconscious for some hours; his face was much bruised and cut, and the scalp severely wounded by the sharp edges of stone he had fallen against; there was a discharge of blood from both ears, which continued in small quantities for two or three days. Fracture of the skull was suspected at first, but could not be detected. On recovering the shock he complained of misty vision, had great intolerance of light, pain in the head, and vomited from time to time during the night following the accident. The next day the symptoms of reaction were such as to call for bleeding with two dozen leeches, the application of mustard cataplasms to the back of the neck, the administration of an effective purgative, and an antimonial saline. He was kept in a dark room, and perfectly quiet for about ten days, and at the end of a fortnight all alarming symptoms subsided, and in three weeks he was discharged, with the caution to apply to me on the slightest return of the sickness, dimness of vision, or pain in the head. With the exception of ordering an occasional aperient, he did not require further treatment, as the wounds healed kindly, and, I must add, he attended most strictly to my injunctions as to his diet and the avoidance of stimulants, &c.

Case 2.—Mr. ——, a cavalry officer, a tall, stout young man, weighing between thirteen and fourteen stone, was thrown out of a tilbury, by his horse taking fright and running against the gate-post of the barrack-yard; he was thrown out, and pitched on his head and shoulder. The result was concussion of the brain, contusion of the shoulder-joint, and fracture of the clavicle. The concussion of the brain displayed itself by insensibility, which did not, however, continue above half an hour, and during the evening the pulse rose to near a hundred, and he became hot, irritable, and restless. He was now bled in the arm, took a purgative, and had his feet put into hot water mixed with mustard. The clavicle was not bandaged till next day, as from the swelling and pain in the shoulder it required fomentation for some time, and it was not desirable to apply bandages till some hours had elapsed. For two or three days the head symptoms continued alarming—pain, intolerance of light, &c. These, however, gradually subsided, and no danger was apprehended, and I discontinued seeing him, though he was still under the care of the surgeon of the regiment, absent at the time I first saw him. I heard afterwards that he was an imprudent young man, and difficult to manage, though he completely recovered, it was thought, from the effects of his accident, but that about nine months after it, he got leave of absence to visit his relations at Devonport, took a short trip by sea, was violently sea-sick, and died comatose from the effects a few days after landing. We may fairly infer that serious injury had happened to the brain from his fall, and that the congestion and straining from the sea-sickness acted upon a material already injured and shaken by the previous concussion. I never heard whether a post-mortem examination took place or not.

Case 3.—A gentleman riding home one dark night at a good pace, came suddenly upon some sheep resting on the road; his horse fell, and the rider was thrown with considerable violence on his head; he was removed to a cottage at the roadside, and I was sent for. I found him cold, totally insensible, pupils dilated, pulse scarcely perceptible, a wound of the scalp just above and behind the ear; there was a discharge of bloody froth from his mouth, and his appearance was altogether most deathly and alarming. His limbs were not injured. A warm cordial was given, or rather poured down the throat, ammonia applied to the nose, gentle friction made on the feet and legs, and the body wrapped in a warm blanket. The propriety of moving him was the difficulty to my mind, but after reflection, and waiting till the body was warm and the pulse had returned, I decided it would be safer to run the risk of an immediate removal than defer it till reaction was fairly established, and the shaking of a carriage would be more acutely felt; he was therefore removed to his residence, about five miles distant. At the expiration of six hours he became conscious, but the pain in his head, the tendency to sleep, and to speak incoherently, vomiting, intolerance of noise or light, or being touched in any way, continued for above forty-eight hours, and some of these symptoms for four or five days. He was bled with leeches, freely purged, and as soon as the vomiting discontinued, took antimonial salines. In the way of food he had little or nothing for the first week, nor did he ask for anything except a drink of tea or toast and water. The head symptoms gradually subsided, though his recovery was tedious and his restoration to health not perfect for above two years from the time of the accident, as the frequent return during that time of attacks of sickness, headache, and irritability plainly indicated; perfect quiet, leeches, aperients, and counter-irritation had to be resorted to from time to time. Ultimately, every unfavourable symptom subsided, and he is now apparently a strong man.

The long duration and the frequent return of these head symptoms for so long a period after the accident, induce me to think that this was something more than a case of simple concussion. We know, from experience and from the publication of many striking cases, that injuries to the head, blows, falls, &c., though apparently recovered from, may and do often produce some lesion of the cerebrum, which, though it may lie comparatively dormant for years, ultimately brings on a fatal attack, and on examination of the brain after death, morbid thickening of its coverings, abscess, effusion, a blood or apoplectic cyst, or softening of its structure, may be found to exist.

Case 4.—Mr. G——, on taking a fence of post and rails, while hunting, fell on his head and his horse upon him. He was insensible, and continued so for above an hour—cold, almost pulseless. He had received a blow from the horse on his head, as well as the shake from the fall: the blow of the horse's shoe was to be seen on his scalp, for it had cut through his hunting-cap, which had doubtless saved his life. I let him remain on the ground some time, just supporting his head a little, wrapping his body and feet in a coat some one was kind enough to lend, untied his neck-cloth, and then poured gently a little wine into his throat, but found it was useless, as he made no effort to swallow. After a lapse of near an hour, we got a carriage, and removed him to the nearest residence, when he was put to bed, wrapped in hot blankets, and was able to take a little negus. Not being willing to remain at a stranger's, though he would have had every comfort and necessary attendance, I removed him, in an easy carriage, some seven or eight miles, to the friend's house where he was visiting. During his removal, he fainted twice, and took a little brandy-and-water. He passed a sleepless night, full of pain, and could scarcely move, as his shoulder was much contused, and his

sides tender to the touch; indeed, I suspected, though I could not satisfactorily ascertain, that one or two of his ribs were broken, for he could not bear a minute examination of them, and I was more uneasy about the head symptoms than anything else. Next day he was bled freely with leeches, took a purgative and a saline, and was kept in a dark room, on the lowest possible diet. For two or three days he saw objects either double or indistinctly, and his hearing was painfully acute, with a sensation of a "whizzing in his ear;" but at the expiration of a week all these symptoms had left him, and he was comparatively well, with the exception of his inability to dress himself, from his contused shoulder and the bruised state of the muscles of his arm and back. He left for the south at the end of the week, as he was obliged, from his engagements, to do so, not of course perfectly well, but sufficiently recovered to travel. I heard afterwards, that about a year after his visit in Yorkshire, he took what was described to me as a form of low fever, and that he died after a short illness. I never have been able to hear the precise particulars or symptoms of his fatal illness, or whether a post-mortem examination was made.—*Lancet.*

INCOMPETENCY OF FEMALES OF NEW HOLLAND TO PROCREATE WITH NATIVE MALES AFTER HAVING BORNE CHIDREN BY A EUROPEAN.

By T. R. H. Thomson, M.D., Surgeon R.N.

The very just remark of Locke—"All that is to be found in books is not built upon a true foundation," was forcibly recalled to my mind of late, by noticing that some of our physiological and medico-legal writers have copied into their works, almost without comment, the very extraordinary statement made by Count Strzlecki in his Physical History of New South Wales (published 1845), to the effect, that when once a female of the aboriginal tribes of Australia has borne a child to a European or white, she ceases entirely to reproduce with males of her own race. A statement so utterly inconsistent with all the known facts connected with the history of the human race, induced me in 1849, during my sojourn in New South Wales, to make particular inquiries, both from natives and settlers of acknowledged observation and veracity.

On informing some of the Broken Bay and Hunter River blacks that such had been reported of their "gins," or women, they scouted the idea altogether, assuring me that it had occurred repeatedly for native women to bear children to their husbands after having cohabited with, and borne *copper-coloured* children to Europeans. Indeed, their accompanying remarks were not at all flattering either to the distinguished traveller who originated, or to myself who then reported, the anomaly. Among the settlers to whom I referred the matter, nearly all expressed themselves surprised at the statement; one of them (Mr. Coulson), whose knowledge of the Moreton Bay natives was very considerable, repudiated altogether this new feature in the history of the aborigines, averring that he had seen it happen several times among the King Bar tribe, the Lady Plains tribe, and Logan Plains tribe, for "gins," or native women, to have black children to their native males, after having had copper-coloured children to squatters or settlers. And to confirm this, a gentleman (Mr. Hayes) who recently returned from New South Wales, after living fourteen years near the Bogan and Mole tribes on the Macquarrie River, and who is now residing near me here (in the Isle of Man), informs me that Count Strzlecki's statement is erroneous, and could only have been imposed on him by some ill-informed or designing persons. He states that a black "gin," at his station on the Macquarrie River, had a copper-coloured child by the European servant of a neighbouring settler; and that this "gin" afterwards joined her native husband and tribe, and had a perfectly black child, without any European trace. And he (Mr. H.) saw both the elder or copper-coloured child by the European, and the younger or black child by the native father, with their mother, not more than six months ago, at his station. He says, moreover, that he would have no difficulty in adding several similar cases, which had come under his notice; but such a startling fact had never reached him, or he would have collected abundance of evidence to refute it.

That the native woman should sometimes become sterile after a period of concubinage with a European is not denied; nor is it to be wondered at, when we take into consideration the change of life which follows on placing herself under the roof of the white settler. From living in a state of nature, with irregular and uncertain diet, exposed to every vicissitude of climate, with no other protection than a few opossum skins, or a roll of bark, or of the "tulka," she enters on a more regular life, partakes of regular meals, and sleeps no longer exposed. But even with this alteration for the better, she does not bear to the white man more prolifically than she would to her native husband; on the contrary, her fecundity appears to decrease,—for on partaking of the white man's comforts, she is a recipient of his vices; she passes much of her time in a half-inebriated state, smoking tobacco and drinking ardent spirits whenever they can be procured. Indeed, it is well known, that among the chief inducements for the native female to remain with a European, are the rum and tobacco with which she is supplied *ad libitum*. Can we then wonder, if, after some years spent in a manner which must militate against her capabilities for procreating, more than her previous rude mode of life, she returns to her tribe with a broken constitution, and probably past the usual term of life for conception (they seldom bear children after thirty years of age) to prove in such instances sterile?

We readily admit that wherever our settlers are commingled with the aborigines in Australia, the native race disappears, and partly from the infecundity of the females. This, however, does not arise from any deviation of Nature's laws, as is attempted to be proven; but because the European, wherever he takes his civilization, takes with him his vices also; and the miserable energy stricken aborigines (scarcely ever sober), noticed by the traveller so commonly around the settlements in the bush, afford too striking evidence of the cause of decline in the native tribes.

Nor must we omit to mention another and sad feature to account for the rapid decrease of the aboriginal population—infanticide; which is now well ascertained to be very prevalent among them, and which is not likely to be diminished by their connexion with the white people—nay, we would suspect the reverse. The "gin," or native female, knows that her white paramour is anxious, rather than otherwise, to preserve the half-caste offspring, and she has no duties which prevent her attending to such; but when she rejoins her tribe, in addition to all her other labours, she must, if she procreates, be further burdened with her children; and it is to be feared that one great reason of their decline is the destruction of the helpless offspring, merely to avoid the trouble which they involve.

As well might Count Strzlecki, or any other authority, refer to the cause he assigns, the gradual disappearance of some of the South American tribes, after Pizzaro's invasion; or of the North American tribes since the United States have sent their hardy pioneers into the far west, as do so in the case of the aborigines of Australia.

We all know that many tribes of both North and South American Indians are extinct; and that among other causes of their decline there may have been some influencing their fecundity. But the principal causes have been, the altered habits, the diseases, the enervating and depraving vices, which the European has taken with him in his pretended civilization. That the various races of mankind can commingle and procreate with each other, without losing the capability of reproducing with their peculiar division of the species, is abundantly proven wherever the white man has turned his steps. Let it be North or South America, India, Africa, Japan, China, or Polynesia, the traveller will now find the half-caste mulatto, the Creole, the *medio-brancho*,—too often the elder brother of the jet black, the brown or olive, thorough bred children, to confirm what is now confidently asserted, to hold good of the aborigines of New Holland.—*Edin. Monthly Jour.*

PALPABLE SIGNS OF SOLID INDURATIONS AND ENLARGEMENTS IN THE ABDOMEN.

By C. J. B. Williams, M.D., F.R.S.

Solid bodies of flattened shape are met with in the abdominal walls, beneath the integuments, or between the abdominal muscles and peritoneum. In the former situation they can be felt to move freely on the muscles. When attached to the abdominal peritoneum, they remain fixed during the movements of respiration, which would carry them a little up and down were they attached to the abdominal viscera—indurated patches in the situations, I have known both of a caco-plastic, and of a malignant nature; the latter being distinguished by its penetrating through several tissues, and presenting nodular irregularities.

A *thickened state of the coats of the intestines* is of common occurrence, and in most cases of chronic diarrhœa can be detected by careful palpation in the region of the cæcum, or segmoid flexure. The thickening results from a low inflammation of a subacute kind, and is usually attended with occasional attacks of diarrhœa or dysentery. In feeling for these intestinal thickenings, some variation of manipulation may be necessary in different parts of the abdomen. The cæcum is usually quite superficial and prominent, and its thickening may be detected by gentle pressure, meeting with more resistance than is felt on the opposite side, while percussion elicits a hollow sound. The ascending and transverse parts of the colon lie deeper and require deeper pressure to test their resistance, which is to be distinguished—that of an enlarged liver, by being sonorous on percussion—the thickened segmoid flexure is distinguished by deep rotatory pressure, when it will roll under the fingers like a large curved cord.

The same tactile exploration will detect thickening of malignant nature, which is distinguished from inflammatory deposit, in assuming the form of a circumscribed tumour; both from being developed as nodular masses, and from the disposition to involve and agglutinate contiguous tissues.

Malignant disease of the stomach, when affecting the pyloric end, and involving the duodenum, colon, and pancreas, in most cases forms a tumour, which may be felt in the epigastric region. The tumour often pulsates, from the motion of the subjacent aorta; but the pulse is in one direction only, and not diastolic, or enlarging at each beat as in aneurism. The tumour is distinguished from the liver by being deeper seated. Scirrhus of the cardia cannot be detected by touch.

Solid massive tumours in the abdomen, as those of the liver or spleen, present certain characters in common. The *liver* may enlarge in every direction, and in most cases may be detected by palpation, as well as by percussion and inspection. The most common mode of enlargement is downwards, with more or less fulness, when it may be felt by its resistance as compared with the opposite side; and in extreme cases, the lower margin may be felt to be distinctly as a rounded ridge. It is important to take notice of the degrees of induration of enlarged liver. The soft enlargements are in many cases tractable under remedial measures; especially, those which increase and liquefy the biliary secretion. In some cases of indurated liver, benefit may also be derived from the same means. In these we do not feel the granular and uneven surface as in the more formidable kinds of cirrhosis. Neither do we find the failing appetite, increasing jaundice, breathlessness, fluttering pulse, and the ominous arcus senilis, which are indications leaving no hope of real recovery.

Cancerous tubera of the liver are often very palpable, and are known by being rounded, flattened, or umbilicated with central depressions.

The *spleen* lying deeper than the liver requires deeper pressure for the appreciation of alterations in its size—the fingers must also be passed obliquely upwards, and to the left. When greatly enlarged, it comes into contact with the walls of the abdomen under the whole margin of the left ribs, from the spine to the epigastrium; it occupies the whole lumbar, iliac, and hypochondriac regions, and may extend even across the mesial line. In all these localities, it is felt as a heavy solid body, generally smooth and even on its surface, except on the right outline which is often uneven.

The *kidneys*, from their deep situations, are not so easily made the subject of tactile examination. For this purpose, it is necessary to displace the superjacent intestines, by a rotatory pressure of the hands. In making this (as all abdominal: Ed.) examinations, it is often necessary to divert the patient's attention, in order to prevent the contraction of the abdominal muscles.

Bulky enlargements of the kidneys are readily detected in the lumbar region, and in front. Cysts in the kidney, and its expansion by the purulent products of chronic pyelitis, may thus be distinguished. Malignant disease is recognized as a tumour, which has the additional diagnostic symptom of hæmaturia.—*London Journal of Medicine.*

COD-LIVER OIL IN JAIL CACHEXIA.

By Caleb Rose, Esq., F.R.C.S.

From the extensive trial which has been given to cod-liver oil, the profession is now able to form an opinion of the value of this medicine in certain diseases; and the author believes he is right in stating that those who have had large experience in the use of the oil esteem it a medicine of great utility. The diseases in which cod-liver oil has been found most beneficial are those which are termed scrofulous, and the author has found it so useful in a particular form of scrofula, that he has thought it might not be uninteresting to record the result of his experience in this form of disease. The form of scrofula to which he alludes is that to which prisoners are liable who have been for some considerable time confined in prison. Dr. Baly, in a very interesting article in the Medico-Chirurgical Transactions, has shown that amongst prisoners who undergo a long term of imprisonment there is a high rate of mortality from tubercular diseases. In the last seven years the author has seen several cases of this scrofulous cachexia amongst the prisoners confined in the prison at Swaffham; and it appears to him to be different to the ordinary forms of scrofula met with in general practice. The men who have been the subjects of it have not been robust at the time of their entrance into the prison, but they were not at this time apparently suffering from scrofula or any other disease. They had all been in prison six months before symptoms of scrofula appeared; most of them eight months; and their term of imprisonment was twelve months, and in one case, the author believes, two years. The symptoms of the disease are these:—The man is observed to look paler and thinner than usual; he is very much depressed in spirits; has no appetite for his food; sleeps badly at night, and at that time, also, frequently has profuse perspirations; there is slight diarrhœa; the pulse is quick, irritable, and feeble. With those symptoms, the author has in every case found some of the cervical glands more or less enlarged, and, moreover, they continue to enlarge very rapidly. In the first five years three of the men died in prison, two of very rapid phthisis (one of them of sudden and large hæmoptysis), the third of tubercular peritonitis. The others who were seriously affected with this scrofula were discharged from prison before their proper time, and, I have since learned, recovered speedily after their liberation. Those who suffered in a minor degree were carried on to the end of their term of imprisonment by care and indulgence. Rather more than two years since we began to treat these cases with cod-liver oil, and with the best effects. As soon as a prisoner begins to show that marked deterioration of general health which is so likely to end in the development of scrofula, he is put upon the oil; and in every case the author has seen the man gain colour and flesh, and become restored to health. The two men who first took the oil had the cervical glands much enlarged (in one of them suppurating), and as they had still to remain some months longer in prison, it was thought that they must have been discharged before the end of their term; however, after taking the oil a month they improved steadily, and eventually left the prison at their proper time, in as good health

as when they entered it. Since these two cases there have not been any so bad, as the oil has been administered in good time to those men who have shown that deterioration of health, which appears to be the commencement of scrofula; and certainly their health has apparently been entirely restored by this valuable medicine.—*Prov. Med. Jr.*

INJUDICIOUS PRESCRIBING.

The following remarks are made with a view of calling the attention of the medical profession to a few essential points which are often not duly considered while writing prescriptions. Some of the errors and contradictions are, doubtless, the result of inadvertence, which may have arisen from interruption by the patient, inquiries from the attendant, and other causes, which need not form part of this communication.

Therapeutical agents of great value are sometimes produced at the expense of decomposition, which at first may not seem desirable; it shows, therefore, a want of justice to criticise too severely the formula a practitioner may choose to adopt, but there are instances when an advantage of this kind is not gained; to such, then, my allusions will for the most part apply.

The prescriptions selected have been received to be dispensed, and in each case come under my own observation:

℞ Liq. ammon. acet., ʒij.
Sp. ammon. arom., ʒj.
Sp. æther. nit., ʒj.
Acid. sulph. dilut., ʒij. Mft. guttæ.

In this mixture there is a solution of ammonia with sulphuric acid, a combination which could afford but little relief in any variety of disease.

℞ Ext. taraxaci, ʒij.
Sp. ammon. arom., ʒiv.
Inf. rosæ co., ʒvss.
Sodæ carb., ʒij. Mft. Mist.

The above objection may here again be urged, while the variation of colour obtained by the manipulation of different individuals, might create serious apprehension of an error being committed.

℞ Magnes. sulph., ʒj.
Antim. pot. tart., gr. j.
Inf. rosæ co., ʒvj. Misce.

We now have emetic tartar with an acid and the astringent matter of rose leaves; a decomposition of the salt necessarily follows, and its efficacy is, to a great extent, impaired.

℞ Unguent hydrarg., ℈j.
Aloes. barbad., ℈iiss.
Sodæ carb., ℈j. Mft. ope sp. nitri dulcis massa, in pil. xxiv. dividend.

This formula is peculiar in two respects. An interview with the medical gentleman was not practicable, as he resided at a distance. Under the circumstances, pil. hydrarg. was employed, but more recent prescriptions have been sent in which the ointment has been persisted in, so the deviation would, perhaps, not have been sanctioned. If this form of mercury is considered eligible for internal use, it would be better to leave the choice of an excipient to the dispenser.

℞ Acid tannic, gr. xxiv.
Infus. cuspariæ, ʒvij.
Syr. mori, ʒss.
Tinct. aurant., ʒiij.
Zingib., ʒj.
Opii, Mxviij ft. Mist.

Inf. cuspariæ cannot be considered a good vehicle for the administration of tannin, tannate of cusparin being formed, and an inelegant appearance given to the medicine.

℞ Morphiæ acet., gr. iss.
Tinct. scillæ, ʒj.
Syr. tolut. ʒiij.
Sodæ biboracis, ʒss.
Mist. acaciæ, ʒj. M.

On adding borax in the above proportion, the gum is instantly precipitated, and the whole mixture reduced to a condition unfit for the purpose intended.—*Mr. Andrews in Phar. Jr.*

GENERAL REMARKS ON THE DIAGNOSIS OF TUMOURS OF THE NECK.

By Dr. P. Redfern.

This always presents great difficulties when the tumours are of large size, only slightly painful, and fluctuate indistinctly. If a complete and accurate history of the case cannot be obtained, more than a general diagnosis may be impossible; but when the precise position of the tumour at its commencement can be made out, when its relations to the larynx and trachea, and its mobility in regard to them and the surrounding parts when it was of small size, can be ascertained, together with the rapidity and manner of its growth, there will be little difficulty in arriving at a satisfactory conclusion.

A *tumour* developed in the substance of *the thyroid body* presents itself in the front of the neck, is usually larger on one side than the other, is firmly connected with the larynx and trachea, moves freely with the larynx in deglutition, and when it is displaced laterally by manipulation. The other features vary with the nature of the tumour.

In ordinary bronchocele (hypertrophy) the swelling is soft, projecting, elastic; without fluctuation, pain or tenderness on pressure; it occurs usually in early life, in the female sex, and in particular districts of country; it is simple in its nature throughout, and presents no tendency to degeneration or change of structure; it in no way interferes with respiration or deglutition, nor does it affect the patient's health or comfort until it becomes of very large size, when difficulty of respiration and deglutition, with frequent headaches, occasion the greatest distress, and may end in the death of the sufferer.

In *cystic disease of the thyroid* the nature of the tumour becomes manifest, sooner or later, by the presence of fluctuation in one or more cysts, by a glairy, serous, or serosanguineous fluid escaping readily along a grooved needle when introduced, the fluid containing no cellular formations when examined microscopically, or having such a structure as is inconsistent with the idea of the existence of cancer—by the formation of the tumour taking place at or after the middle of life—by its slow and painless growth, and by the slight inconvenience it occasions as long as its size is not very great.

In cancerous disease of the thyroid (usually scirrhus) the tumour appears between 45 and 65 years of age, is of great and uniform density, and generally painful; it is developed rapidly, and may attain a large size in the course of a few months; it accompanies the larynx in its movements, but shortly limits their extent by attaching the organ to the surrounding parts; it occasions great difficulty of deglutition and respiration from an early period; hoarseness, cough, and spasmodic action of the muscles of the larynx and pharynx come on and increase in their intensity—the distress and anxiety of the patient, his sallow complexion and emaciation, marking him out as the subject of a steadily advancing and destructive malady.

In *medullary cancer of the thyroid* the surface of the tumour may be even and tense, or indistinct fluctuation may be perceived, the other characters, depending on the steady infiltration of the surrounding textures, distinguishing the disease from other tumours of the same part.

Enchondromatous tumours are to be recognized by their great density, the slowness of their growth, and the absence of any signs of the extension of the affection to the surrounding parts, and of general evidence of the existence of malignant disease.

The diagnosis of *tumours of the neck, not connected with the thyroid body*, is to be established by reference to the general characters which distinguish them in other situations, every particular of their history and mode of growth being carefully ascertained as essential points, and sufficient care being exercised lest the presence of a quantity of coagulable fluid, in the interior of a cancerous tumour, lead to the belief that it is of a cystic character.—*Ed. M. Jr.*

TREATMENT OF DIARRHŒA BY SULPHURIC ACID.

Case 1.—John G——, No. 6, Belgrave-buildings, aged 48, was seized on Sunday evening, the 24th of August, with violent vomiting and purging, attended with great pain in the bowels. Pulse weak, skin cold, and countenance very pallid. Ordered to bed, and to take half a drachm of diluted sulphuric acid (P.L.) in ten drachms of water. When I called at his house early on Monday morning, his wife informed me that he was quite well, and had gone to work.

Case 2.—Charles P—— was desired to come to me on Friday, the 29th of August, by the Rev. Mr. Brown of Halkin-street. He was labouring under diarrhœa, which had been going on for some weeks. Gave him one dose similar to the above, and told him to come the next day if not relieved. He did not call until Sunday morning, when he stated there had been no action of the bowels since he swallowed the acid. Has not called again.

Case 3.—Charles B——, aged 22, came to my house on Sunday evening, the 31st of August. Complained of vomiting and purging. The diarrhœa had been going on for four days. Gave him half a drachm of the acid in water, with orders to come again if necessary. Up to the time of writing this account I have not heard from him.

Case 4.—Ellen J——, aged 24, of No. 8, Eaton-court, consulted me on the 4th of September. Had diarrhœa thirty hours, with considerable pain in the bowels, and nausea; had twelve motions during the last four hours. She had a mixture, with two drachms of the acid in six ounces of water, with directions to take three tablespoonfuls directly, and two tablespoonfuls after every loose stool.

5th. Had five motions in the last twenty-four hours; free from pain and nausea. Medicine to be continued.

6th. Bowels regular. Discharged cured.

Case 5.—Elizabeth W——, aged 40, living at No. 5, Belgrave-buildings, came to me on the 4th of September. Diarrhœa two days, with griping pains; vomiting and headache. Ordered her the acid as in the other cases.

5th. Much relieved. 6th. Cured.

Case 6.—Thomas L——, aged 7, of No. 8, Eaton-court, was seen by me on the 4th of September. Had diarrhœa two days. Prescribed for him diluted sulphuric acid, twenty-five minims; water, four ounces. Mix. One large spoonful to be taken after every loose stool. He took three doses, and is perfectly well.

Case 7.—J. W——, aged 40, residing at No. 8, Belgrave-buildings, had vomiting and purging of a severe nature, attended with pain in the bowels. These symptoms yielded to half a drachm of the acid.

Case 8.—During the night of Saturday last, I was called out of bed to a lady in Wilton-street, whom I have attended for many years. I found her in a state of great agony, suffering from violent spasms in the bowels, constant vomiting, great prostration, with diarrhœa of three days' standing. I gave her half a drachm of the diluted acid in water, and sat at her bedside for two hours, when I left her, free from pain and sickness.

I saw her on Sunday morning at ten. There had been no vomiting; neither had she had one motion since she had taken the acid, but she complained of nausea. Ordered her twenty minims of the acid. I saw her in the evening at seven. There had been one comfortable evacuation; pulse improved; tongue clean; nausea subsided.

At my morning visit, I was consulted by her daughter, a young lady, aged 17, who was (after I had left her mother in the night) attacked with vomiting and purging, attended with griping pains. I gave her twenty minims of the acid, with directions to repeat it if necessary. At my visit at seven in the evening, I found the vomiting had quite ceased, and there had been no action of the bowels after taking the above dose. The patient was free from pain.

Monday morning: mother and daughter perfectly free from diarrhœa, pain, vomiting, and nausea. Directed the acid to be discontinued.—*Mr. Griffiths in Lancet.*

TREATMENT OF ANEURISM BY GALVANO-PUNCTURE.

A case of popliteal aneurism has lately been treated at the Hospital St. Pierre, at Brussels, by M. Seutin, chief surgeon to the hospital. The patient who is aged 31, and debilitated by syphilis, was first seen when the tumour in the ham was the size of a hen's egg; in nine months' time it grew to be as large as the head of a fœtus of six months. Galvano-puncture was tried by the consent of the whole hospital staff; and after three very painful operations, each averaging half an hour, and giving intense pain, M. Seutin was obliged to tie the femoral artery, as the galvano-puncture had not yielded any favourable results, and the patient did not wish to submit to it again.

The ligature came off on the tenth day after the deligation of the vessel, and the wound was quite cicatrized at the patient's residence (he had insisted upon leaving the hospital) on the twenty-sixth day. The man now began, in spite of repeated warnings, to walk about, and went several times up and down stairs. Inflammatory symptoms soon set up in the sac; the latter suppurated, and the skin over it became so thin that the tumour was opened with the lancet, and purulent matter and grumous blood evacuated. Seven days afterwards the patient had an attack of hæmorrhage; his life was saved by timely compression of the femoral vessel; but M. Seutin thought that hæmorrhage would certainly recur if the artery were not tied in the ham. The sac was therefore largely laid open; but when the end of the vessel was found, it was so weak that pieces of it remained in the dressing forceps with which it was seized. M. Seutin, therefore, cauterized it with the hot wire; the wound in the ham now gradually closed, and the patient was quite well six weeks after the laying open of the sac. Galvano-puncture does not seem to have been a favourable forerunner to the ligature.—*Presse Médicale Belge.*

REVIEWS AND NOTICES OF BOOKS.

ON THE PREVENTION AND CURE OF SPINAL CURVATURES, AND DEFORMITIES OF THE CHEST AND LIMBS; being the result of many years' experience. By Mrs. Godfrey. London. 1851. 8vo. pp. 90.

It is somewhat a novelty to be called upon to notice in the pages of a medical periodical a professional treatise from the pen of a female, and we feel ourselves placed in rather an embarrassing position in having to pronounce an opinion upon the merits of a medical work written by one of the gentler sex.

In the preface to the treatise, Mrs. Godfrey states her reasons for coming before the public as an author:—

"The writer of this little work has frequently and earnestly been requested to lay before the public her plan of treatment for spinal curvatures, and other deformities of the body; and long ere this would have been prompted by her desire of lessening, in some degree, the amount of human suffering, to comply with the request but for the following reasons—namely, the desire for increased knowledge and experience, the want of time, in consequence of constant attention to patients, and the hope that some one more suitable for so important a work would undertake it. But though many able works on spinal and other deformities have been published, in which she has seen much to admire, and much that has served to confirm her own views of the subject, she has hitherto met with none to which she could refer the reader for a knowledge of the treatment which, after long experience, she has found to be the most successful, and therefore now ventures to recommend."

We are next informed how it happened that the author came to make spinal deformities her study:—

"My attention was first directed to this subject by the circumstance that patients who came to consult my husband for affections of the spine, &c., frequently requested me to be present during their examination, or to examine them myself previously to their seeing him. Among these there were

some who, suffering greatly from spinal curvature, entreated that something might be attempted for them; and the distress which they manifested awakened in me an anxious concern to discover if possible a remedy or relief for so painful a malady."

Having determined "to study the anatomy of the human frame in order to ascertain the situation of the nerves and muscles," the author tells us, with great *naiveté*, of her delight when she discovered "that every muscle terminated in a tendon," and that "each tendon was inserted into a bone," "as this discovery gave her a clear idea of the plan of treatment to be adopted, and was the lever of her hopes."

Mrs. Godfrey's style is rather discursive, and the treatise is deficient in both index and table of contents; we gather, however, from a perusal of the first part, that she relies principally in the treatment of spinal curvature and other deformities upon frictions with animal oil, combined with other manipulations and regulated exercises; she does not employ mechanical supports or machinery, with some slight exceptions, and she objects to the constant recumbent posture. Perhaps, however, her views respecting spinal deformity and its treatment will be best illustrated by quoting one of the cases which she adduces in support of her views:—

"A lady, 26 years of age, was brought to me with an extensive lateral curvature of the spine. Her body was perceived to lose its balance when she was about 14 years of age. . . . . The spine had three curves, one above the left shoulder, from the first dorsal to the fifth; on the right side there was another, from the fifth dorsal to the eleventh; and on the left side the curve extended from the first lumbar to the fifth. The first, second, and third dorsal ribs were elevated two inches above the top of the shoulder, the corresponding ribs on the right side being inverted in proportion to the convex on the left. Through the extensive curve at the right shoulder, five of the dorsal ribs were raised up over those which had sunk down, causing the blade of the shoulder to be raised up nearly horizontally over them; thus pushing the head of the bone of the arm, and twisting the arm round, so as to make the first finger rest on the side, with the hand turned to the front of the body. The supports had pressed against the side of the elevated ribs, and forced them back over the curved joints, creating the appearance of a second spine, raised five inches above the column. The intercostal muscles were exceedingly congested through the expansion of the ribs.

In proportion to the enlargement of the right side, the muscles on the left were attenuated, the ribs inverted, and the point of the shoulder was sunk into a deep hollow. The left lumbar curve had produced a convexity of the short ribs, and displaced them; the points of two were forced up under the angle of the long ribs; the other three were pushed down upon the pelvis, and the muscles between the ribs were so thickened as to feel like a hard bony substance; the ribs were elevated three inches above their natural position. On the right side there was a corresponding hollow, and the angle of the long ribs could not be felt. The intercostal muscles of the short ribs were entirely depressed, so that the whole of the hand could be laid in the hollow without being seen. There was a corresponding displacement of the bones of the chest; on the left side there was a deep hollow, on the right, an elevation of four of the ribs; and while the right clavicle was inverted, the left was elevated. The patient who, while standing, was of the middle size, appeared when sitting no taller than a child of seven years of age.

My first impression was that nothing could be done, but after a little consideration I was led to hope, from the success of other cases, that a longer period of time being given, with adaptation of treatment, some relief might be afforded. The promise to make the attempt greatly cheered the patient. Her supports were removed; but from the use of them the muscles had become so weakened, that when she came to me the following day without them, she was obliged to be placed in the recumbent posture in her carriage. Her debility being so great, the friction and exercises were proceeded with very gradually; her strength, however, daily increased, and after a month she was able to employ a considerable part of every hour before dinner, and an hour in the evening, in various exercises. . . . . By the end of three months, the ribs on the right side so approximated, that a bag of skin, which would have held a pint of liquid, hung loosely down, having lost its elasticity through its having been so long stretched by the expansion of the ribs. The exercises, however, soon brought back its contractile powers, and the muscles on the left side grew so fast, and so expanded the ribs, that she could feel the point of the shoulder, which she had not done for some years previous. In proportion to the growth of this side was the diminution of the size of the other; the shoulder had returned to its right place, allowing room for the arm to fall into its proper position. In three months more the shoulders were both low, and sloping; the neck had resumed its natural appearance, the enlargement over the left hip was much lessened, and the spine much stronger; the middle curve had straightened two inches, and each of the others one inch. Her appearance now, with a thin shawl over the shoulders, was almost natural. In consequence of domestic affliction she was compelled to return home. After a few months she came back to me again, and continued altogether two years. At the end of this time the back was nearly straight, each curve being within a quarter of an inch of the perpendicular line; the flesh of the left side looked like that of a young child, and with a thin covering over her shoulders no deformity could be seen, her figure looking good and natural."

The remainder of the first part of the volume is occupied with deformities of the limbs. In the second and concluding part, Mrs. Godfrey notices various points connected with dress, position, exercise, diet, &c., "by which curvatures and other deformities are frequently produced," but the length to which the case we have quoted extends prevents us from doing more here than simply enumerating the matters discussed in this part.

STUDENTS' NUMBER OF THE MEDICAL PRESS.

THE STUDENTS' NUMBER will be published on WEDNESDAY, the 29th of OCTOBER. Regulations of Universities, Colleges, and other Institutions for Medical and Surgical Education, properly authenticated, should be transmitted to our Office *without delay*, in order to secure a proper and careful analysis of them. Advertisements of Lectures and Hospitals, Books, Surgical Instruments, and Medicines, should be forwarded in sufficient time to secure a proper arrangement of them.

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, OCTOBER 15, 1851.

INTERPRETATION OF THE NEW DISPENSARY LAW.

WE solicit attention to the following note from Dr. KNOX. It explains the nature of a difficulty suggested in a late number, and will be of use to those circumstanced so as to encounter that difficulty. We are at all times glad to give publicity to such comments and explanations, convinced that the obvious meaning and simple interpretation of this law will be better elicited by discussions amongst members of our profession than by the subtleties of "counsel learned in the law." The formation of the Dispensary Districts will prove the most difficult passage in the tactics of the ensuing campaign, and will cause the greatest amount of discontent and disappointment; we must therefore be prepared to deal with it in such a spirit of forbearance and resignation as we can well command; always recollecting that, even looking to one's own interests exclusively, the two sides of a question are worth examining:—

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—With reference to the point raised by the subscribers to the Annadown Dispensary, and commented on in your last

number, I beg leave through your columns to acquaint the Medical Attendants of the Irish Dispensaries, "that the question of uniting the adjoining electoral divisions of different unions, in forming dispensary districts, received the earnest attention of the Acting-Committee when the bill for regulating the medical charities was before parliament."

As far as I am aware, the point was first mooted in one of the resolutions, drafted for the approval of a public meeting of our body in Belfast in 1850, and the following are the exact terms in which it was passed:—

"That it would be an improvement to form the dispensary districts, where convenient, by the junction of conterminous electoral divisions of adjoining unions, on the principle adopted in the bill, with reference to the district hospitals."

Having forwarded copies of these resolutions to the proper quarters, I subsequently adverted to the same point in a letter which I had the honour to address to Sir W. Somerville, and which was published in the Report of our proceedings at the Dublin meeting; and again, when in London, I did not lose sight of the matter. Finding, however, that fiscal and other objections militated against the adoption of our views, we did not think it prudent to press the matter too far, or to throw any obstruction in the way of the bill, by having an amendment moved on the question at issue.

I have no grounds, therefore, for believing that our suggestions in this respect were acted on; on the contrary, I think that the junction of electoral divisions of different unions to form a dispensary district in the mode suggested, would be contrary both to the plain reading and the spirit of the act. It may be alleged that in some cases this may prove inconvenient, but certainly not more so than the clause which clearly directs that, in the formation of a dispensary district, no electoral division shall be divided, the effect of which will be, that in some instances the poor of a locality may have five or six miles to go for medicine and advice, whilst an adjoining dispensary may be within one or two miles of their residence. The whole question, therefore, in the opinion of the committee, will be best left in the hands of the commissioners, as these points were, no doubt, maturely considered whilst the bill was under discussion. With reference to the formation of districts under the new law, it will be well to bear in mind that, according to the evidence of Mr. George Cornewall Lewis before a committee of the House of Commons, the average size of a medical district in England is 10,000 acres, the maximum being, except in some peculiar mountain districts, as in Wales, 15,000 acres; whilst the average extent of the Irish dispensary districts, under the late system, was 13,000 statute acres. The maximum population of a medical district in England is 15,000. With all due respect, therefore, I conceive that the attempts made in some unions to determine the limits of the new dispensary districts are premature until the guardians have before them the order of the commissioners for their formation, in carrying out which, according to the wording of the sixth clause, they are "to have regard to the extent and population," and with reference to which it is very possible that the commissioners may lay down some general rule for their guidance, which would prevent a great deal of trouble and facilitate a satisfactory arrangement of the matter.

Requesting that you will pardon this trespass on your columns, I remain, sir, very faithfully yours,

ALEXANDER KNOX,

Hon. Secretary to the Committee of Physicians and Surgeons of the Irish Fever Hospitals and Dispensaries.

Strangford, October 6, 1851.

FEVER HOSPITAL LAW EXEMPLIFIED.

WE copy the following, although unacquainted with the particulars of the "move" which it records. It evidently affords an example of the working of the Fever Hospital clauses of the poor-law act, and shows how these clauses may admit of mischievous interpretation to suit the views of persons having little jobs to promote. To remove the unfortunate victims of fever from a well-regulated fever hospital, and from the care of such a man as Dr. KINGSLEY, to an "auxiliary house," may answer a purpose; but whether it might not increase the mortality is another question. We have no right, however, to condemn a law which admits of such execution as this, nor a board of guardians which interprets it so honestly. They unanimously resolve to do what is right, and what more can be expected. Minorities must be found every where having views of their own; and it is the business of majorities to keep them from doing mischief, as they have in the present case:—

ROSCREA UNION.

The usual weekly meeting of this board was held on Friday last. After the usual preliminary business was gone through, the following remonstrance from the inhabitants of Roscrea was read by the deputy chairman, after which he spoke for some time on the admirable management of the present fever hospital, and went into the several items of expenditure for the last year, clearly showing that no good result could occur from the change that was in contemplation by a very small section of the board:—"Gentlemen, We, the undersigned ratepayers and inhabitants of the town of Roscrea, having heard that it is the intention of your board to remove the fever patients from the present fever hospital to the Brewery Auxiliary Workhouse, beg leave respectfully to remonstrate with you against the adoption of such a course, inasmuch as it is calculated to endanger the health of the town, the locality being thickly inhabited, and that portion of the river from which they are supplied with water must of necessity be impregnated with the drainage that comes from that building." [Here follow the names of about seventy of the most respectable inhabitants of the town.] Immediately after the above document was read, the following resolution was unanimously carried—"Resolved, That Dr. Kingsley possesses the confidence of this board, and that our thanks be conveyed to him for his ability, zeal, and economy in discharging the duties of the fever hospital." One of the guardians observed that this was but an empty compliment to the doctor, but that at some future time he hoped a more substantial one would be paid him, for there was no physician stood higher in the estimation of the ratepayers and public at large; and few were more successful in the treatment of fever cases. The board very soon after dispersed, quite determined not to permit any change from the present fever hospital to the Brewery Auxiliary Workhouse.—*King's County Chronicle.*

MEDICAL AND SURGICAL EDUCATION.

EVERY week, every medical journal now contains one article or more on the abuses in medical education, and the relaxation of discipline in the Colleges; while at the same time the demands are loud and long for the summary ejection from amongst us of all notorious delinquents. The article we copy below, however, appears in a journal not strictly speaking either medical or surgical, although of value to both physicians and surgeons. It suggests, or rather announces, an experiment in education, a trial of the "voluntary principle:" providing the student with instruction, and leaving it to himself to accept or reject it. We say student, although that student is but a chemist's apprentice, because we see clearly that the ground so foolishly abandoned by the apothecaries is about to be occupied by this class of tradesmen. How far this "voluntary principle" could be adopted in Schools of Medicine or Surgery remains to be proved. It has been in course of trial partially for some time; prescribed lectures, although paid for, not being attended, or perhaps not delivered at all. Teachers in their headlong race to join the scramble for the pupils' money, seem to have lost sight of every other consideration, and hence the present state of affairs. We must wait to see the result of this trial of the voluntary principle in the Pharmaceutical Society, but in the mean time we recommend the gentlemen of the lecturing and grinding interest to consider well the prospect before them. They, we believe, have been hitherto the advocates of a free trade in medical teaching, without check or limit, and to call for "protection" to keep up prices now would not be very

consistent. Be this as it may, here are the lucubrations of our pharmaceutical contemporary :—

COMPULSORY AND VOLUNTARY EDUCATION.

In our number for November, 1843, we adverted to this subject, and contrasted the system of compulsory attendance at hospitals and medical schools with the experiment of voluntary education, in which the Pharmaceutical Society had at that time recently embarked. The candidate for a diploma as a medical practitioner is required to produce certificates of attendance at a recognized school during a period prescribed by the regulations. Certain courses of lectures, the number of which is defined, must be attended ; that is to say, certificates to that effect must be produced. In the case of the apothecary, indentures of apprenticeship are required, and in the universities evidence must be produced to show that the candidate has undergone a sufficient preliminary education. Notwithstanding the stringency of these regulations, and the exertions which are made to coerce the student into the right path, the result is not uniformly successful. In every school or college there are "reading men," who derive the full benefit from the advantages before them ; and "fast men," who evade the regulations, neglect their studies, and trust to the "grinder" for success at their examination. The object with the latter class of students is to *pass* with the least possible trouble, and to obtain a diploma representing the minimum amount of knowledge allowed by law. Without compulsion, they would scarcely take the trouble to study at all ; and, under any circumstances, are not likely to attain more than a superficial knowledge of their profession. Other students, and we believe a considerable proportion, may be more easily led than driven. They are sensible of the value of knowledge and experience in the art and science of their profession, and, if properly directed and furnished with the means of improvement, they require no act of parliament to induce them to study. It has always been a disputed question to what extent the *vis à tergo* is necessary or desirable for the propulsion of students. There are many advocates of voluntary education, who consider that when a youth has left school, and embarked in the avocation which is to be the future business of his life, he might be left to his own discretion, and that common sense would dictate the importance of industry. At all events, they maintain that each individual would find his level ; that those who neglect the advantages of improvement which are before them in early life will be themselves the sufferers, and that their fate will be a warning to others. This principle may be a correct one in regard to those avocations in which want of skill and knowledge only injures the individual himself, but in a profession relating to the public health and the treatment of disease, the question of qualification affects the public as well as the practitioner. It is on this ground that acts of parliament have been passed to regulate and enforce the education of medical men. In the absence of the requisite powers for extending this provision to the department of pharmacy, the Pharmaceutical Society was established on the voluntary system. Not only is the passing of the examination voluntary, but the mode in which the candidates qualify themselves is left to their own discretion. Lectures are provided, and other means of instruction are offered to the student on very moderate terms, but attendance is not compulsory. The further experiment of throwing open the lecture-room during the present session to all members and others connected with the society, will test the voluntary system to the fullest extent. It will be seen how many young men will volunteer to accept education when offered free of charge.—*Phar. Jour.*

THE THREE PHARMACOPŒIAS.

It is remarkable that the making of new pharmacopœias has led to new demands for better ones. The suggestions in the annexed extract are reasonable, but how can they be adopted, seeing that the proverbial disagreement of doctors forbids coöperation. No two Colleges can agree on any subject, and why on this, which affords as many admirable causes of difference as the subject of doctor-making itself. Equal doses of colchicum, prussic acid, and opium, may seem very desirable to the uninitiated, but when "sad and learned" men cannot agree as to the dose to be selected what remains but to have three doses. Out of all evils, however, comes good, and in the present case it is particularly so, for this very confusion of doses makes the employment of good and thoughtful physicians, surgeons, and apothecaries necessary. We really can have little commiseration for those who are poisoned by mountebanks or "cheap-and-nasty" advertisers :—

It is a matter of great regret, that in a kingdom under one government and one system of laws, there should be an entire want of uniformity in the preparation and strength of compounds daily employed for medicinal purposes. We have no National Pharmacopœia. England, Scotland, and Ireland, each claims its own pharmacopœia as the only true, infallible, and perfect model of a work of this description. It will doubtless appear strange to those who are not versed in the mysteries of the apothecary's shop, that there should be any variation in the strength of British medicines *bearing the same name ;* and that a prescription prepared in Edinburgh or London should be likely to produce widely different effects, but such is nevertheless the fact. It is, we believe, quite true that a uniformity of strength in the pharmaceutical preparations of the three kingdoms is the exception to the rule ; and in some cases the diversity exists among compounds of a very formidable nature—overdoses of which are likely to produce fatal effects. A writer who has lately commented upon the inconveniences attending this want of uniformity, states that "the acetum colchici of Dublin is three times the strength of the acetum colchici of Edinburgh and London. The acetum opii of Edinburgh is three times the strength of the acetum opii of Dublin. The hydrocyanic (Prussic) acid of Edinburgh is nearly twice as strong as that of London and Dublin. The London solution of hydrochlorate of morphia, and solution of acetate of morphia, are twice as strong as the analogous preparations of the other two colleges." Other diversities might be pointed out ; but these are surely enough to show that if we wish to avoid fatal accidents, the attention of our colleges is urgently required to this subject. The language of medicine should be the same in the three countries, especially in regard to compounds the use of which may cause danger to life. Some years ago, owing to a similar want of uniformity in the French Codex, several persons were poisoned under the prescription of a physician who had been accustomed to employ a weaker form of prussic acid than that in use in the infirmary to which he had been recently appointed. There is nothing in the climate of Edinburgh to render it necessary to use prussic acid of twice the strength of that of London or Dublin ; nor is there anything so peculiar in the constitutions of Englishmen as to render it indispensable that the preparations of morphia should be twice as strong as those found to be sufficient for the stomachs of Scotchmen and Irishmen. These differences may endanger life, unless care be taken by the prescriber to mark the nationality of the preparation which he selects. Inadvertence or forgetfulness may, however, lead to the omission of this precaution ; and it is probable that some hundreds of practitioners are either not aware of the differences or of the degree to which the *similarly-named* preparations actually vary in strength. If fatal accidents have not already occurred from this want of uniformity, it is no reason why our collegiate authorities should delay those steps which are required for so necessary an improvement in our pharmaceutical system. The present plan is not merely dangerous to patients, but it is embarrassing to prescriber and dispenser ; it places either or both under a risk to which they ought not to be exposed ; and it daily exposes an Irishman to be poisoned in London by morphia, or an Englishman to be poisoned in Edinburgh by prussic acid. Considering the position occupied by the three colleges, it is clear that no satisfactory reason can be assigned for this diversity in our pharmacopœias. We do not now express an opinion whether it is better, in a scientific or philosophical point of view, to employ the Edinburgh or London prussic acid : if the respective authorities cannot settle this point, and they agree with us that people ought not to incur the risk of being poisoned in the interim, then there is an easy way of compromising the matter. Let the weaker preparations be taken as the most safe to the public under a change ; and if Edinburgh will give up her prussic acid, Dublin her colchicum, and London her morphia, we shall be able to proceed amicably and safely, if not philosophically. Whatever is done, and whatever sacrifice may be made, there should be, without delay, a perfect uniformity throughout the three kingdoms in the strength of the powerful medicines to which we have above referred.—*Med. Gaz.*

REPLY OF PROFESSOR SIMPSON OF EDINBURGH TO HIS ASSAILANTS.

In our Number for October 1st, we copied a letter from the *Lancet* reflecting on Dr. Simpson, and at the same time one from Dr. Simpson which was inadvertently placed as a reply to it. The following is the reply, and it appears to us a satisfactory one:—

To the Editor of the Lancet.

Sir,—For some time I was at a loss to determine whether it was not my duty to repel by very different measures from the present, the attack in the *Lancet* of September 20th, published under the assumed name of "Isaac Irons." Among the circumstances which have principally decided me to follow the present simpler method, is the unanimous conviction which all my medical friends who have either written or spoken to me on the subject have expressed on one point,—viz., that there is in the medical profession only one individual who does use, on professional subjects, language so indiscreet as that of the well-known writer in question; and that, after all, this individual was scarcely legally responsible for his own outbreaks of violence.

The circumstance of my being President of the Royal College of Physicians of Edinburgh, is a matter which seems particularly to annoy "Irons;" for he alludes to it more than once in his letter, and in one point of view it is in itself the best answer to his intemperate insinuations. The election to the Presidentship of the College of Physicians is in the hands of the resident fellows, or, in other words, in the hands of those who are living and practising as medical men in Edinburgh, and who consequently know me and all my professional doings and conduct infinitely better than any one residing at a distance, like "Irons." And "Irons" may rest fully assured that had I ever been guilty in the slightest degree of any impropriety, moral or professional, such as he seems anxious to impute to me, I should never have been elevated to the Presidentship of the College of Physicians; an honour which I confess I greatly value, not only because it is the highest honour to which a Scottish physician can possibly aspire, but also because I was elected to it (and I believe elected unanimously) by the free votes of my fellow practitioners; and that too at an age when the office has been conferred upon few.

On various professional points "Irons" and I have the misfortune to disagree. Whether he or I be right I most willingly leave to time and experience (the only true tests) to determine; and of their ultimate verdict I have no fear. But certainly any existing diversity as to this or that method of practice, is no reason whatever why one man should attempt to brand another who chances to disagree with him with the imputation of quackery. I have never, on any occasion, made a secret of any point or peculiarity in my practice. It has been open and patent to the study and criticism of all. I have always taught every part and item of it to my pupils, and, as many foreign and British physicians can testify, I have always gladly shown it, and its full results to my professional brethren. Of course I am not foolish enough to imagine that my brethren of the medical profession will, without due consideration and experience, adopt any practical doctrines in uterine pathology that I or any one else may please to propose. Any difference, however, in opinion and practice may assuredly be stated, and, if necessary, discussed between professional men in the language of gentlemen. But on this, as on other occasions, "Irons" strangely seems to suppose that the medical profession of England are weak-minded enough to mistake mere personal abuse and scurrility for argument, while he evidently forgets that it is, on the contrary, generally acknowledged that such weapons are seldom or never used, except in cases where all proper and legitimate arguments are actually wanting.

In more than one point "Irons" passes even these bounds, and recklessly imputes to me opinions which I at least never held. Take one for an example: he charges me with an attempt "to substitute the Cæsarian section for the induction of premature labour." I never held or dreamed of such a doctrine; and I am sorry I can only designate this allegation as a deliberate untruth. Further, I would beg him to remember that the mere repetition of an untruth cannot (as he seems to fancy) betimes convert it into a truth.

I shall neither weary you nor myself by refuting, as I intended, some of "Irons'" other studied misrepresentations and misstatements. Let me only revert to one more. Among other matters of blame, "Irons" states that to me, "more than any other individual, we are indebted for the profligate use of the speculum," and for "pessaries which have justly been designated infernal and impaling uterine machines." The first of these accusations I utterly and indignantly deny. The essays that have appeared upon uterine disease in the pages of the *Lancet* have, I know, done more than any other English writings to spread the use of the speculum in Britain; and neither in the *Lancet* nor elsewhere have I, at least, ever written in its favour. In fact, I have always held and taught that, by the advocates of the speculum, greatly too much was expected from its employment; and that it was often had recourse to in cases and diseases in which it was entirely uncalled for, because it was entirely useless. Among the various patients whom I have at the present moment here under my charge from London, five out of the number are, or were, the subjects of aggravated retroversion. In all of these cases the speculum had been employed in London; in three properly, because there were in them inflammatory lesions to treat; but in the other two improperly, as I conceive, because the instrument was unnecessary as a means of diagnosis. One of these last two patients was a patient of "Irons" himself. For some weeks during the last autumn she wore an "infernal and impaling" intra-uterine pessary, with complete relief to the symptoms under which she had been suffering for years. After the instrument was for some time finally withdrawn, she for the first time told me that she had previously consulted "Irons," who informed her, as I had done, that her disease was retroversion; that he recommended her to use a pessary; but advised the pessary to be withdrawn and reintroduced once or twice daily; that (though he has declaimed so much against the speculum, and though the speculum was assuredly not required in this, a mere instance of uncomplicated retroversion) he insisted upon employing it; that when she objected to its use, he and a medical friend who was with him argued that it was required "a thousand times a day;" that in using it he placed her upon a common drawing-room sofa; and that altogether (although she has now seen several obstetricians) his questions and examination were, she declares, more indelicate and painful than any others to which she has ever been subjected. Dr. Duffin of Langham-place knows the case I refer to.

In the last number of the *Lancet*, in your Notes to Correspondents, you adduce the following as a kind of reason for admitting into your pages such letters and attacks upon me as that written by "Irons." "Dr. Simpson," you observe, "will not fail to recollect that his name is systematically published as that of one of the editors (conductors) of the *Edinburgh Monthly Journal of Medical Science*, a work which habitually contains very gross imputations on the reputation and conduct of the hospital physicians and surgeons of this metropolis. In consequence of not having repelled such attacks, we have been accused of exercising undue forbearance, and even of showing culpable partiality towards Dr. Simpson and his colleagues of the northern journal." The journal in question was assumed by its present conductors principally with a view of promulgating the doctrines of the Edinburgh Medical School, and of defending these doctrines from the misstatements to which they were systematically subjected in your own and in other journals. For instance, from "culpable partiality" (?), you admitted years ago into your own pages various anonymous letters from "Irons" and others (or rather, I should probably say, from "Irons" under various

other names), containing attacks and misrepresentations regarding myself and my practice, nearly as unprincipled and as violent as that which has just appeared in the *Lancet*. Since becoming one of the proprietors and conductors of the *Monthly Journal*, I can honestly declare that I have never written one single word of blame or imputation against any London medical man. You must excuse me, however, for adding, that after what has happened, I do not pledge myself to be equally lenient for the future.

In my previous letter to you I mentioned that I was informed by one of your first surgeons in London that "he was attending the foot of a noble duke, whilst a celebrated homœopathist was attending to his grace's stomach and constitution." In your last number I am urged by one of your correspondents "to state fairly and openly the name of this surgeon." But the surgeon in question told me this circumstance in the course and confidence of private conversation, and I could not but view myself as breaking through every rule of good faith if I complied with your correspondent's request.—Yours, &c., J. Y. Simpson.

THE INSURANCE COMPANIES *v.* THE MEDICAL PROFESSION.

Resolutions adopted at a Meeting of the Faculty of Physicians and Surgeons of Glasgow, held upon the 1st of September, 1851, in reference to the Payment of Fees to Medical Referees by Life Assurance Companies.

1. That this faculty has long maintained the principle, that medical referees, the ordinary attendants of the parties desiring life assurance, ought to be suitably remunerated for their trouble in replying to the usual queries on behalf of the assuring companies; and that the parties granting the assurance ought to pay this fee, as it is obviously for their safety and guidance that such information is afforded.

2. That in conformity with these views, the faculty, so long ago as 1st June, 1835, passed a law, requiring every member of their body to refuse replying to these queries unless a specified fee were transmitted along with the schedule, and this law has, from that time, been steadily adhered to and acted on.

3. That in carrying out the above views, the faculty regret being obliged to record, that till of late, with a few honourable exceptions, they have met with the most uncompromising opposition from the insurance companies, especially those of more early establishment; and although within the last two years several even of these have made a movement in the right direction, yet this has been so long deferred, and so obviously only a yielding to the pressure of circumstances, as to deprive the concession of much of its value.

4. In this position of affairs, it has given the faculty much pleasure to observe some of the more recently established insurance companies, not only frankly acknowledging the justice of the principle so long contended for, but spontaneously offering a liberal compensation to the members of the medical profession for the very valuable information and opinions it is not unfrequently in their power to afford; and to such companies the faculty beg, in this public manner, to offer their best thanks.

5. The faculty also take this opportunity of recording the sense they entertain of the important services done to the profession, in this matter of remuneration to private referees, by the editors of the *Lancet*, the *Medical Gazette*, and *Medical Times*, to whose intelligent and steady advocacy, they are aware, they mainly owe whatever favourable change may have taken place in the conduct of the assurance companies towards the profession.

6. The faculty beg also to state, that whilst in 1835, in their anxiety to have the principle of remuneration established, they were indifferent as to the actual amount conceded; they now feel called upon, in justice to themselves, to intimate to the agents of all assurance companies, that the fellows of their body will not, in time coming, pay attention to any schedule of queries submitted to them with a reference to any species of life assurance, unless such schedule of inquiry be accompanied by the fee of one guinea, if the sum proposed to be insured exceeds £300, and 10s. 6*d*. if the sum is £300, or under.

7. The faculty order these resolutions to be printed, and copies sent to the editors of the London and provincial medical press, to the agents of the various insurance companies, and to the presidents of the royal colleges of Edinburgh, and the other medical corporations throughout the kingdom, inviting their concurrence and coöperation.

CORRESPONDENCE.

OPERATION OF THE DISPENSARY ACT.

KILLALOE DISPENSARY.

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—I enclose with this a series of resolutions adopted at a meeting of the subscribers to our dispensary, held this day, the Lord Bishop in the chair. They refer to a subject which, I am informed, has already occupied your attention—viz., the formation of Dispensary Districts in localities situated in more than one poor-law union: a subject, the importance of which should be strongly impressed upon those who may have the carrying out of the new Medical Charities' Act. Our position here is peculiar, as this town stands almost at the bounds of *three* unions; and unless some such arrangement as we suggest be effected, either an injustice will be done to our medical officer, as pointed out in the third resolution, or if (to obviate this) he be appointed to the three districts that must otherwise be formed, a heavy and unnecessary expense will have to be undergone in providing three houses, three caretakers, and three sets of *fittings up*, where one of each would suffice. The advantage of uniting districts hitherto, from fiscal considerations, divided, has been recognized in an act passed in the last session of parliament, which provides that whenever the magistrates of petty sessions' districts situated in different counties, not adjoining each other, shall think it advantageous, those districts may be amalgamated into one; and the magistrates are empowered to exercise jurisdiction in all cases coming before them, even though the offence may not have been committed in the county for which the magistrates hold the commission of the peace. Now, the propriety of a like junction for dispensary purposes of electoral divisions situated in different unions is obvious. The fairest principle to act upon would undoubtedly be, to select some central spot (a town when practicable) as the head of the district, and to unite to it as many electoral divisions, in whatever unions situated, as will form a district *convenient to the poor, and properly manageable by the medical officer*. If any other principle be adopted, the present dispensary doctors will be unfairly dealt by, the poor will be put to great inconvenience, and the ratepayers will suffer to an extent that they do not calculate upon at present. The only objections to this junction, that I have heard, are, the inconvenience that may arise in keeping separate accounts in each union for the one district, and the difficulty of fairly apportioning the amount of expense that each should be charged with. But those objections are more apparent than real; for as the accounts of each electoral division are *at present* kept separate, and as each is rated in proportion to the number of paupers it contains, so, as respects medical relief, a similar principle (as regards the different unions) can easily be acted upon, and no difficulty or confusion need take place. I would not trouble you, sir, at such length if the question were one purely local, but as many other localities must be situated in some respects like ours, the question is one of general interest.—I am, sir, your obedient servant,

W. Edwards, Clk.,
Treasurer to the Killaloe Dispensary.

Killaloe, October 11, 1851.

Resolutions referred to.

1st.—That the subscribers to this institution feel themselves called upon to represent to the Commissioners of Medical Charities the difficulty which may arise in forming a convenient Dispensary District in this locality, owing to its peculiar position with respect to the poor-law boundaries, the present district being partly in the Scariff union, partly in that of Limerick, while the Nenagh union immediately adjoins it, and is connected with it by the bridge at Killaloe.

2nd.—That it is therefore the opinion of this meeting, that it would be beneficial both to the ratepayers and to the poor requiring medical aid, that the new district should if possible be formed so as to take in the neighbouring electoral divisions of the above-named unions, inasmuch as by this arrangement one dispensary establishment and one medical officer would be sufficient, where otherwise three would be

required; and such a salary can be obtained as will secure the services of a highly qualified practitioner, without bearing heavily on the rates.

3rd.—That unless some arrangement, such as the foregoing, shall be carried out, an act of substantial injustice will be done to our present medical officer, inasmuch as if his district be confined within the limits of one of the poor-law unions, its extent must of necessity be so circumscribed, that a much lower salary than he at present has will be deemed sufficient remuneration for his services: an effect which appears to be contrary to the intention of the new Medical Charities' Act, which expressly provides for the maintenance of existing rights.

4th.—That we take the liberty of suggesting that a most convenient district for this neighbourhood would be one consisting of the following electoral divisions.

[Here follow the names of electoral divisions, which it is unnecessary for us to print.]

THE MEDICAL COMMISSIONER.

Another week has passed and no appointment made. This does not trouble us, because it looks like deliberation and a determination to select a worthy officer to discharge the proposed duty. We have only to repeat what we have so often said on the subject: Let us have an honest and respectable man, and we will answer for the result. With such a person the profession can and will coöperate; but with one of directly opposite qualities, they must always act with reserve and suspicion.

THE BRANDING OF DESERTERS.

It appears that the Surgeons of the British Army have had a respite of the sentence passed at the Horse Guards, ordering them to do execution by branding on all deserters or other delinquents found guilty of offences liable to this punishment. It is supposed that this will prove a quiet method of rescinding the obnoxious order.

DUTIES OF ASSISTANT-SURGEONS IN THE NAVY.

Director-General of the Medical Department of the Navy.

(circular.) Admiralty,

Sir,—Having deemed it advisable to require journals from the assistant-surgeons of her Majesty's ships, in addition to those already established for the surgeons under whom they serve, and also from assistant-surgeons in charge of stores, in addition to those they now send, I have given directions for a supply of the blank journals in question to be forwarded to the several naval hospitals and depôts at home and abroad, to be furnished to the assistant-surgeons on their application for the same. You are therefore to make the necessary demands accordingly, and to give a receipt for what you may obtain.

In keeping up these journals, you must exhibit your talent, industry, and neatness; and no reason short of serious illness will be admitted as an excuse for neglecting this important part of your duty, which must be certified by the surgeon.

The journals are to be transmitted with those of the surgeon (to whom they must be delivered in the event of your leaving the ship), or, when there is no surgeon, by any other safe conveyance by which expense shall not be incurred.

You are to acknowledge the receipt of this letter.—I am, sir, your humble servant,

———, Director-General, &c.

———, Assistant-Surgeon, H.M.S. ———.

ASSISTANT-SURGEONS.

1. Every assistant-surgeon serving under a surgeon is to keep a journal, in which he is to enter, in brief but concise terms, every circumstance affecting the health of the crew.

2. In this journal he is daily to note, in a tabular form, carefully ruled, and similar to that which follows, the minimum, maximum, and, as nearly as can be ascertained, the medium temperature of the external air; and in the same manner the temperature of the deck on which the men are berthed, and the stoke-hold in steamers when under steam; the direction and force of the winds; the kind of weather; geographical position of the ship, or latitude and longitude; and, if he has the opportunity, the height of the barometer, together with any unusual meteoric phenomena that may be observed.

3. He is also to note when the issue of fresh and salt provisions to the ship's company takes place; when lemon-juice is issued, and when its use is discontinued.

4. When infectious or contagious, epidemic or endemic, diseases make their appearance on board, he is, by a careful investigation into all the circumstances connected with the first cases, to give an account of their origin, of the manner in which they were contracted, of their progress and decline; mentioning whether they were communicated to other ships, or extended to the shore, and also the means taken to cure or eradicate them.

5. He is to place on record the names of men killed, drowned, or seriously injured; specifying the cause of death, the nature of the wound, and how inflicted; and also the names of men invalided, sent sick to hospital, or to any other place out of the ship.

6. When boats are detached, in unhealthy localities, he is to endeavour to obtain, and to place in his journal, a nominal list of the men sent in them; stating the time of their departure and return, and also the influence which the climate, the weather, or other agencies, appear to have had upon them.

7. He is carefully to observe and detail the effects produced by particular localities on the health of the men, whether resulting from exposure on board or on shore, on duty or on leave, or from over indulgence in articles of food or drink. For further details required to be noticed occasionally in these journals, the assistant-surgeon's attention is especially called to the 30th, 31st, 32nd, 33rd, 34th, and the 40th articles of the Surgeons' Instructions.

8. He is to keep a copy of the surgeon's daily sick book, from which yearly, on the 31st December, or up to the time of his leaving the ship, he is to make out and to insert in his journal a nosological table, according to the form now in use for the quarterly returns.

9. As these journals are, in some respects, intended to supply the deficit or loss of the surgeon's accounts, the surgeon is to afford the assistant-surgeon every facility for obtaining the details necessary for their completion; but as they are further and more especially intended as a means of enabling the Director-General to form an opinion of the ability, zeal, and the attention to his professional duties of the assistant-surgeon, every assistant-surgeon is most distinctly to understand, that unless his journal be sent into office in a creditable manner, it will effectually prevent the Director-General recommending him to their lordships for any special appointment, or for promotion.

N.B.—When the first table has been completed, and the remarks are written out, the assistant-surgeon must make out for himself the forms for succeeding months. It is calculated that two or three pages will suffice for recording the events of the month, but occasionally, according to the importance of the matter to be communicated, more space may be required; the journal may then be enlarged by adding to it foolscap paper of a large size. Each journal to include about one year.

A PRACTICAL HINT TO NAVY CAPTAINS.

We had, on a former occasion, to complain that the good intentions of the Admiralty Board were often defeated through the insolent vulgarity of the captains of our ships of war; we see, however, that this is not very likely to occur in future, as the Lords have taken the matter into their own hands, and have personally superintended the disposal of suitable accommodation to the medical officer. We read in the *United Service Journal* the following announcement:—"We have the pleasure of recording the fact, that during the visit of the Board of Admiralty to Devonport, their lordships went on board the Virago sloop of war, and themselves selected a cabin for the assistant-surgeon. The captain has given up his steward's berth, which is turned into an office, and the office and dispensary have been given to the assistant-surgeon, so that he has now one of the best cabins in the ship. This is proper feeling on all sides, and we trust the good example set by their lordships will be sufficiently indicative to all 'pig-whiffins' of what is expected of them by those they are bound to obey." Our contemporary deserves the thanks of the naval assistant-surgeons for the zeal he has displayed in their cause.—*Prov. Jour.*

PROFESSOR PORTER'S SURGICAL WORKS.

OBSERVATIONS ON THE SURGICAL PATHOLOGY OF THE LARYNX AND TRACHEA,

Chiefly with a view to Illustrate the Affections of those Organs which may require the operation of Bronchotomy.

OBSERVATIONS ON THE SURGICAL PATHOLOGY AND TREATMENT OF ANEURISM.

By WILLIAM HENRY PORTER, M.D,
Surgeon to the Meath Hospital and County Dublin Infirmary, Consulting-Surgeon to the City of Dublin Hospital, and Professor of the Theory and Practice of Surgery in the Royal College of Surgeons in Ireland, &c. &c.

Dublin: Fannin and Co., Grafton-street.

Mr. Porter is preparing for publication his Lectures on VENEREAL DISEASES, with additional Notes and Illustrations.

NOTICE TO THE MEDICAL PROFESSION IN IRELAND.

THOSE Medical Gentlemen who have not yet filled up and returned the Circular for the insertion of their Names, Qualifications, &c., in the forthcoming Medical Directory for Ireland, are requested to do so without further delay, as names cannot be received later than the end of this month. Any gentleman who may not have received a Circular is requested to intimate the same to the Editors, 4, Adam-street, Adelphi, London.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT
AT
G. O. AND CO.'S MEDICAL ESTABLISHMENT,

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. ANXIOUS to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention*; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. AND CO. CONTINUE TO BE SUPPLIED WITH THE FOREIGN MINERAL WATERS FRESH FROM THEIR VARIOUS SPRINGS.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

TO PHYSICIANS, SURGEONS, AND DRUGGISTS.

BROWN'S CANTHARIDINE BLISTERING TISSUE,

PREPARED FROM PURE CANTHARIDINE.

AN elegant Preparation, vesicating in much less time than the Emp. Lyttæ. P.L., easily applied and removed, and will not produce strangury or troublesome after-sores. It has received the sanction and commendation of many of the most eminent Practitioners in the kingdom.—*In Tin Cases, containing twelve feet, 6s. 6d.; and small Cases of six square feet, 3s. 6d. each.*

BROWN'S TISSUE DRESSING,

An elegant, economical, and cleanly substitute for all ointments as a dressing for Blisters, and may be called a companion to the above.—*In Tin Cases, containing twelve square feet, 1s. 6d. each.*

Extracts and Editorial Note from the New York Journal of Medicine.

"March 1, 1850.

"BROWN'S CANTHARIDINE TISSUE.—It presents peculiar claims to our notice in the inflammatory diseases of females and children, in whom the unpleasant consequences which so often follow the application of the Emp. Cantharides are most apt to occur. We have found it a reliable and peculiarly safe vesicant, and from the many trials we have given it, we are satisfied that it deserves the attention of the Medical Profession.

"Accompanying this article is a very simple and neat dressing."

From the Medical Examiner and Record of Medical Science for May, 1850, published in Philadelphia.

"We have received from Mr. George D. Phelps of New York specimens of Brown's Cantharidine Blistering Plaster and Dressing, with which our readers are doubtless familiar as a new and exceedingly neat preparation, easy of application and certain in their effects. We have given them a fair trial and find they fully answer our expectations."

"Army Medical Department, January 16, 1847.

"The Principal Medical Officer of the General Hospital, Fort Pitt, Chatham, reports that Mr. Brown's Blistering Tissue has been used extensively in the Military Hospital, has been found effective as a vesicatory, when carefully applied, and has not been productive of any degree of strangury.

"ANDREW SMITH, M.D.,
"Deputy Inspector-General of Hospitals.

"Mr. T. B. Brown, Druggist,
"Handsworth, Birmingham."

THE MIDLAND RETREAT,

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY,)

For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System,

Under the direction of Dr. JACOB,

Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

Just published, 8vo, pp. 96, price 2*s.* 6*d.*,

A TREATISE ON CATARACT;

Including the Structure of the Crystalline Lens, the Nature of its Opacities, and the Operation for its Removal by Absorption, with the Fine Needle through the Cornea.

By ARTHUR JACOB, M.D., F.R.C.S.,

Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.

Also, lately, by the same Author, 12mo, price 5*s.*,

ROYAL COLLEGE OF SURGEONS.

SCHOOL OF SURGERY.

THE Session 1851–2 will not commence until the 27th of October. Gentlemen, however, residing in Dublin can commence their Dissections immediately on entering their names for the ensuing Winter Course of Practical Anatomy.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

SCHOOL OF SURGERY.

THE Winter Session, 1851–52, will commence on Monday, October 27.

Anatomy and Physiology—Dr. Jacob.
Descriptive Anatomy—Dr. Hart and Dr. Macdonnell.
Surgery—Mr. Porter and Mr. Hargrave.
Practice of Medicine—Dr. Benson.
Chemistry—Dr. Barker.
Midwifery—Dr. Beatty.
Comparative Anatomy—Dr. Jacob.
Dissections by the Professors of Anatomy and the Demonstrators—Dr. Leeson, Mr. Labatt, Mr. T. D. Hargrave, Mr. Malcolmson, and Mr. Morgan.

THE SUMMER SESSION WILL COMMENCE THE 3RD OF MAY.

Materia Medica—Mr. Williams.
Botany—Dr. A. Mitchell.
Medical Jurisprudence—Dr. Geoghegan.
Practical Chemistry—Dr. Barker.

The Fee for each of the above Courses is Two Guineas.

For further information apply to any of the Professors, or to the Registrar. By order,

W. BOYLAN, Registrar.

CITY OF DUBLIN HOSPITAL.

THE Winter Course of Practical, Medical, and Surgical Instruction will commence on the 27th of October.

The Clinical Lectures will be delivered by Dr. Jacob, Dr. Benson, Dr. Beatty, Mr. Hargrave, Mr. Williams, Dr. Geoghegan, and Mr. Tufnell.

Dr. Jacob will deliver a full Course of Lectures on Diseases of the Eye; Dr. Beatty, select Lectures on Diseases peculiar to Women and Children; and Mr. Tufnell on Military Surgery.

Sir Henry Marsh, Sir Philip Crampton, Professor Apjohn, Professor Porter, and Mr. Cusack, give their assistance in cases requiring consultation.

Certificates of attendance are received as qualification by all the Colleges, Halls, and Boards.

DISEASES OF THE EYE.

DR. JACOB will deliver a full Course of Lectures on the Anatomy, Physiology, and Optical Mechanism of the Eye, during the ensuing Session, in the College of Surgeons, and also a separate Course on its Pathology and Diseases, with the Operations required in their Treatment, in the City of Dublin Hospital.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin. London: John Churchill, 46, Princes-street, Soho.

ORIGINAL COMMUNICATIONS.

ON THE VARIETIES OF COD-LIVER OIL.

By M. Donovan, Esq., M.R.I.A.

"We find the different sorts of cod-liver oil indiscriminately sold in druggists' shops, the generality of the physicians never noticing what sort they use."—*Dr. De Jongh of the Hague.*

The great difference observable in the cod liver oils of commerce renders it important to inquire what are the opinions of those who have had the best opportunities of estimating the therapeutic powers of the different kinds. I was the first person in this country that manufactured the oil for medicinal purposes, and was at that time (several years since) under the impression that to produce it as free as possible from taste and colour was a chief object, not on account of any superiority of curative power, but because I conceived that by so doing the repugnance of persons requiring its use would be greatly lessened. According to evidence presently to be adduced, it appears that advantages of greater importance are obtainable by a sacrifice of those which merely relate to facility of administration; the medical efficacy is the legitimate object to which attention should be directed: I shall therefore confine myself to showing that the weight of evidence is in favour of the light brown or deep golden-coloured cod-liver oil.

In this country we have but two designations—viz., the "pale" and the "light brown or deep golden-coloured:" there are many varieties in shade of each; but they may be all resolved into these denominations; and with regard to their relative values as medicinal agents, there seems to be no difference of opinion amongst competent judges.

Dr. Schupman, who successfully treated two cases of paralysis of the lower extremities with cod-liver oil, observes that "this remarkable power belongs only to the brown-coloured oil, the light-coloured losing much of its virtue in its purification." (De Jongh, p. 77.) Richter also "declared the brown-coloured to be the most powerful, whilst to the light he denied any power whatever." (Ibid, 79.) De Jongh has published his researches on the comparative medicinal powers of the three kinds of oil, from which it appears that the times necessary for the performance of the cure were very different. Thus five months and a half were necessary for the cure of rickets with the paler oils, while the same cure was effected in three months and a half by the brown oil: and chronic rheumatism required three months and a half for cure with pale oil, and one month and one-third with brown. These inferences were drawn from a great many cases; and analogous results were obtained in other diseases. De Jongh concludes that "we may ascribe to it (the brown oil) more powerful healing properties than to the other two kinds (the pale kinds). (p. 157.) He adds, "it is therefore fair to assume that the brown cod-liver oil owes its greatest power to the biliary matter and butyric acid which exist in it, in much larger proportions than in the lighter coloured oils." (p. 160.)

The conclusion to which Dr. Bennett, who has paid great attention to this subject, has arrived is that amongst the various kinds of cod-liver oil, the "least beneficial is the white." (Bennett on Cod-liver Oil, p. 175.) Elsewhere he says that, being present at the half-yearly meeting of the Medical Association of Wirtemberg, he examined the three kinds of cod-liver oil presented to the meeting—first, light straw colour almost white; second, golden colour; third, deep chestnut brown: "of these the second or deep golden yellow colour is for the most part used medicinally throughout Germany." (p. 20.)

Some patients inconsiderately complain that the cod-liver oil with which they are supplied has "very fishy taste and smell." It is not wonderful that fish oil should have a fishy taste and smell. But this leads to the disclosure of a miserable fact that, in commerce, we occasionally meet with a so-called cod-liver oil which is not subject to either of these complaints, being in fact derived from poppy seeds, colza seeds, or from the olive by heat and expression; it is thin, limpid, and pale; and its vegetable origin is discovered by the fact, that it is entirely solidified by an acid solution of nitrate of mercury. On this subject, Dr. Bennett says, "when first introduced into the infirmary,

neither the physicians, the apothecary, nor the druggists of the town were enabled to distinguish cod-liver oil from other kinds of oil. On one occasion, I found all the patients taking linseed oil instead of it; and it is a fact worthy of observation that *several practitioners who employed it at that time gave it up as inert.*" Well might they do so.

It is thus that many a valuable remedy has fallen into disrepute by the use of substitutions. An oil has been of late offered for sale by persons who purchase up the livers, intestines, and offal of every sort of fish collected from the fish markets; they melt them, and render the oil pale and clear by various devices. It may also be observed that much of the so-called cod-liver oil is derived, not only from "the livers of different kinds of fish, but from the fat of porpoises and other marine animals." (Quoted by De Jongh from Konow.)

When I commenced the manufacture of cod-liver oil, I caused the gall-bladder which adheres to the liver of the fish to be removed in each case, and gave a direction to that effect in my published essay; for at that time the beneficial effect of the bile was not suspected. Of late, I have discontinued this practice, it being rendered probable by several considerations adduced by writers on the subject, that the biliary ingredient in the oil is of use.

The commercial pale oil is obtained by various objectionable processes; one of the most general methods is the putrefaction of the livers (Mack quoted by De Jongh), a sufficiently disgusting mode of proceeding. This is the method adopted in Newfoundland, the motive being not colour, but the extraction of a greater produce of oil. Pennant thus describes the process: "they take half a tub, and boring a hole through the bottom, press hard down into it a layer of spruce boughs, upon which they place the livers, and expose the whole apparatus to as sunny a place as possible. As the livers *corrupt*, the oil runs from them." The oil obtained from corrupted livers surely ought not to be used as a medicine; in another place I have pointed out the possible ill consequences of such a practice. (See *Dublin Medical Journal*, 1845.)

Another method of procuring the oil pale is to boil the livers in water until the oil be separated, which will then float, and may be skimmed off. Those physicians who attribute the virtues of cod-liver oil, or any portion of them, to the presence of iodine in some obscure state of combination, or to the bile of the fish, as many at present do, would consider that, by the action of water, the oil may be deprived of much of its virtue; accordingly, De Jongh observes that the opinion is pretty generally received that "the pale contains no iodine," and that the presence of the latter is confined to oil of deeper colour.

A third method of procuring pale cod-liver oil is by subjecting it to the operation of chemical agents. Dr. Richter of Wiesbaden on this subject observes, that oil rendered pale by chemical means "has a very weak fishy smell, is similar in appearance to olive oil, and is disposed of in commerce as the only pure oil, but is never used internally in Sweden, and is there considered inert." (Quoted by Dr. Bennett.)

One of the chemical processes is to mix the oil with bones burnt to blackness and powdered: the bones being afterwards separated by the filter. The oil is thus deprived of its colouring matter, and much of its smell. Who will venture to affirm that its medicinal powers are not thus impaired?

Another process is exposing the oil, in thin broad layers, to the action of the sun and air for months. The chemical agency of light in this case is not problematical; the constitution of the oil is certainly changed, and who will deny that it may be injuriously altered. But some manufacturers, impatient of the tedious process of bleaching by sun-light, adopt the more speedy method of exposing it to the action of chlorine. On this last method, the German Translator of De Jongh says—"It is not always because the pale oil appears to contain less powerful qualities, but far oftener owing to the frequent deceptions to which those who employ the pale oil are exposed. It is often the common south-sea oil, or the seal oil of commerce artificially blanched. Meebold remarks that nearly all the white oil of commerce is blanched by chlorine, by which it is rendered not only less powerful, but also equally unpleasant to take." (German Translation of De Jongh by Dr. Carey, p. 125.)

On all the foregoing accounts, I conceive that injury is inflicted on the public by this and other kinds of medical cookery, and that physicians should discourage it. When it is discovered that attempts are made to improve upon Nature by surreptitious and perhaps detrimental means, it appears expedient that the article should be supplied to the public of the colour recommended by those physicians who have most employed it in their practice; and even if this colour presented no other advantage, it will at least be a guarantee that the oil has not undergone any injurious treatment. Cod-liver oil of a deep rich golden colour must possess all the advantages of that important medicine, beside being in the state which protects it from suspicion.

An opinion prevails that genuine cod-liver oil may be distinguished by its property of producing a fine crimson colour when triturated with concentrated sulphuric acid. There can be no test more deceptive. Several fish oils possess the same property; but above all, the test fails by affording the desired tint even when the oil is mixed with a large proportion of vegetable oils.

11, Clare street.

COMPARATIVE VALUE OF NITRE AND COLCHICUM IN CHRONIC RHEUMATISM.

By Dr. Cargill of Newcastle.

These cases have been treated during a period of nearly six years,—*i.e.* between 1842 and 1848, and they have been nearly all in-patients of this hospital, so that I have had them constantly under my own eye, the few not so situated having been out-patients.

I have compared the cases together under as equal circumstances as possible, and have endeavoured to attain as much accuracy as I could by carefully registering them at the time; this register comprising the following features:—Age, sex, duration of malady previous to admission, seat of pains, dose and combination of remedy, time of its employment, result, disturbing or other effects on the system, temperament of the patient, and concomitant treatment.

I shall first consider these points in reference to what was observed in the colchicum patients, and then in those treated by the nitrate of potash, and shall conclude by recording certain deductions, which I think have unfolded themselves from the various facts, and likewise mention the views I entertain of the pathology and intimate nature of rheumatism.

Of the 43 cases treated by colchicum, 14 only were cured, or about one-third, and the average duration of the treatment was 15½ days; the average duration of the malady before admission being 73 days. In addition to the 14 who recovered entirely, there were 12 relieved, whilst 12 remained no better. In 1 the complaint appeared to be worse, and in the remaining 4, circumstances arose which prevented any positive conclusions from being arrived at.

Dose and combination of the Colchicum.—In rather more than half of those cured, that result was effected by the vinum seminum colchici in the dose of from 15 to 30 drops thrice a day, with a little magnesia and sp. etheris nitrici. In a very few instances 10 grains of Dover's powder were given a few times at bedtime. In 6 out of the 43, the colchicum was given in powder in four-grain doses thrice a day; in one case it was given in six-grain doses thrice a day, and in one case in two-grain doses thrice a day, all combined with pulvis cretæ. In all but the last named it produced vomiting, griping, and diarrhœa in two or three days time, and had to be left off for the vinum with magnesia. Of this latter combination, the dose before mentioned,—viz., mxv. to xxx. with 15 grains of magnesia,

and ʒss. of sp. eth. nit. was the most effectual, and the best borne. When the vinum was given by itself it seemed slower in its curative effect, and when given in ʒjss. doses or ʒj. doses thrice a day, either alone or combined (a measure in a few instances adopted), it invariably had to be left off, from its producing very speedily its usual severe physiological effects, with great depression, and often cramps, the disease remaining at the same time unaffected. I should add, that these results followed even when the above doses were attained to very gradually.

Concomitant treatment.—In 17 out of the 43 cases the warm bath thrice a week was used, and in 14 out of this number manifest relief was obtained. In 10 cases out of the 43, Dover's powder was given in from 10 to 15 grains each night, and in 6 of these cases it was followed by beneficial effects. Cupping was occasionally used, and generally with benefit. Bleeding from the arm was scarcely ever practised, and calomel, Epsom salts, blue pill or colocynth, were used as preliminaries, if constipation existed. As to the seat of the disease, it was in the several joints and muscles. In four cases wherein the rheumatism existed along with sciatica as its chief feature, the treatment by colchicum was fruitless.

Of the 100 cases treated by nitre there were 61 cured, being more more than six-tenths of the whole, and the average duration of the treatment was 13¾ days. In addition to the 61 cured, there were 20 who experienced great relief, but were not entirely cured at the time of dismissal; there were 5 who experienced very slight benefit only, 3 received no benefit, and 3 got worse. In the remaining 8 cases no positive conclusions could be arrived at.

Dose and combination of the remedy.—The usual dose to begin with was ʒij. thrice a day in barley-water; this was adhered to in many cases throughout, but in a large number it was increased to ʒj., ʒiss., ʒij., thrice a day, and in one case ʒiij. every four hours was begun with and continued without intermission for twelve days, without the smallest inconvenience to the patient, who was cured in that period. This was a bad case of 2½ years' previous duration. The dose was often begun with and continued at ʒj., and with no disagreeable effect; sometimes ʒj. thrice daily, and sometimes ʒj. every four hours consecutively.

Being desirous of ascertaining whether the duration of the malady might be shortened, or good in other ways obtained by combining the nitre with sp. nit. antim. tart. and tinct. opii, I adopted this in a considerable number of cases, and the result has shown me that no advantage is derivable from this practice. The dose of sp. of nitre was generally from mxv. to ʒss., or more; that of the vin. antim. mxv., and that of the tinct. opii. mv. to each dose of the pot. nit. Sweating and diuresis were equally produced by the nitre alone as when given in the above combination. Of the three, the tr. opii alone appeared useful by frequently assuaging the severe pain.

Disturbing effects.—It is of great importance to remark that this remedy was invariably administered in a large quantity of warm barley-water—not less than ʒviij. to each dose. When given in the above large doses, without a diluent and demulcent like barley-water, it produces intense griping, with pallor of the countenance and cold perspiration, the pulse and heart's action flagging and coming down, and the greatest anxiety being experienced. This is followed by a dry red tongue, with enlarged papillæ and much thirst. This I had an opportunity of seeing to an intense degree in one case wherein the nitrate of potash in those doses had been administered several times without any diluent by the oversight of a nurse; she gave it in ʒiss. of plain water. I was on the point of applying numerous leeches to the epigastrium, fearing that gastritis was coming on, when the symptoms at last yielded to diluents and warm external applications, leaving no appreciable effects behind.

I shall now mention what were the *disturbing effects on the system* observed to be produced by large doses of nitrate of potash in cases *where it had been duly taken* with barley-water, but had not been well borne by the system. Those effects were seldom manifested, the medicine, when properly diluted, seeming to act mildly and efficiently. When it is not tolerated, however, its effects are primarily on the nervous system. They are these:—General debility of the limbs, especially the lower extremities, and the knees, too, particularly complained of. I have seen this carried to an extent which made the patients believe that they were seized with general paralysis; the whole body seemed to be made of wood, and for some hours it was impossible for them to rise from their seat or to move hand or foot. To this were conjoined general tremblings, and the speech was affected; occasionally the names of things were forgotten or mistaken: there was also giddiness, and a painful rushing sound in the ears. I never in these rare instances saw any distortion of the features, and the symptoms subsided in a few hours by diuretics or copious perspiration. In the event of such results occurring, the chief remedies I should recommend would be hot diluents and hot blankets. The subjects of them will be found generally of the purely *nervous temperament*, especially if associated with feeble power of the constitution. When the sanguine or bilious temperament is combined with the nervous, the remedy is better borne and may be pushed farther; and it consists with my observation that the bilious lymphatic temperament, with its firm, harsh, muscular development, is the one in which this plan of treatment the oftenest succeeds and may be used the most fearlessly, as it is the one on which chronic rheumatism, when once established, displays itself with perhaps the greatest relentlessness.

The *concomitant treatment* was simple, and most generally dispensed with altogether (with a view to ascertain more accurately the value of the nitrate of potash itself), except in cases of severe complication, in which the need for additional means, chiefly local, was urgent. It consisted in occasional warm baths and vapour baths. Cupping and leeching were had recourse to in such cases as showed a concentration of the disease in particular joints, as evidenced by swelling, redness, and acute pain not shifting its seat. In dull chronic pains localised, occasional blisters were applied, and often with benefit; and, towards the termination of the cases, a liniment of ammonia and turpentine was frequently useful in restoring the natural suppleness of the parts. When the pains were so great as to prevent sleep, and to harass the patient in an unusual manner, a draught of muriate of morphia, with solution of acetate of ammonia and water, was given at bedtime. The bowels were kept free by means of occasional light cathartics; and the treatment was generally commenced by giving a dose of calomel and colocynth, followed by a draught of infusion of senna with sulphate of magnesia.

The *diet* enjoined was nutritious, being the ordinary diet of the house—viz., meat once a day, milk, rice, broth. In such cases as presented symptoms verging on the acute, low diet was prescribed—such as milk, tea, sago, &c. In all old standing chronic cases generous diet was found the best, accompanied even by ale, porter, wine, or gin.

In the above 100 cases the *duration of the malady previous to admission* was widely different,—so much so, that no analytic average could be struck with a view to results that would not have a tendency rather to conduce to error than to elucidate truth. I may state in general terms that the length of time in these cases previous to coming under the above treatment was from seven days to ten years, whilst there were a few who could remember no period of their lives in which they had not been victims, more or less, to the complaint. Two months, five years, six years, six months, one year, were the most common periods cited; and it should be remarked that nearly all the cases were of an unusually severe character, and had been under all manner of practitioners; for many, despairing of a cure otherwise, had committed themselves to the tender mercies of unprincipled quacks, from whose fiery ordeal they had emerged with the conviction that now nothing but a residence in an infirmary with the reputation of our own could avail to benefit them!

Sex.—It is remarkable that, of the whole 143 patients, 17 only were women, the remaining 126 being men. The

average age of the women was 35⅔, that of the men 37⅓. From this it appears that, in this part of the country, men are about 8½ times more liable to be affected with chronic rheumatism than women, or for one woman attacked with chronic rheumatism there will be between eight and nine men. This is in all probability owing to the greater exposure of men to cold and wet; for I have found that in all of these cases the exciting cause, when any could be given, was invariably cold and wet, or sudden transitions from a high temperature to the opposite. On referring to MS. notes of M. Louis' clinical lectures on this subject, taken down by me at the time of their delivery at the Hospital of La Pitié, in 1835, I find his experience the same as to the exciting cause—invariably exposure to cold air or draughts (un vent frais).

The difference as to the *frequency of rheumatism* in France and England seems to be very great. Louis says that, out of 100 cases of all sorts treated by him, he only found one of rheumatism; and in the Paris hospitals, during two years, it was rare that rheumatism, whether acute or chronic, ever fell under my observation. That the difference is great among us will appear from the following fact:—On analysing, a good while ago, a number of cases of all sorts, nearly all of them chronic, treated by me in this hospital, embracing a period of five years, and amounting to 959, I found that 86 were cases of chronic rheumatism, being, on an average, 1 in 11⅛th of the whole number. From this I think we may infer that climate exercises an immense difference in this disease; and doubtless the same cause is, in regard to all other diseases, more powerful than we are generally aware of. How else can we explain the entire exemption of some countries from certain maladies? In India and Egypt phthisis is unknown.

I will take the opportunity of stating here, that I believe heart affections to be very uncommon associates with chronic rheumatism; nor do I think that this malady is apt to be *followed* by cardiac disease. In the cases above analysed it was constantly found that such of them as showed heart disease, had been preceded by rheumatic fever, and the heart affection could be traced to that period of acute disease. This is in conformity with the opinion now, I believe, generally entertained—viz., that acute rheumatism is very frequently accompanied by endocarditis, and, without very vigorous measures, is apt to be succeeded by permanent disorganization of the heart. I have seen this hold to the full extent admitted by Dr. Hope, though not perhaps to the degree maintained by Bouillaud. In chronic rheumatism properly so called, heart disease is, in my opinion, a rare occurrence.

In speaking of acute rheumatism I would record here my experience that in patients *under the age of puberty* acute rheumatism seldom or never happens without most seriously involving the heart; and the younger the patient (I have known it occur at five years) the more certainly fatal is this heart affection. I have never seen a single subject in the above category who eventually shook off the heart affection and recovered. And, in addition to the ventricular hypertrophy and dilatation constantly present in these cases, as well as the valvular disease, I must mention a morbid appearance perhaps equally constant, and which I think has been overlooked by pathologists, or only casually if at all mentioned—viz., a tough, dense, false membrane lining the general interior of one or other of the dilated auricles, generally the left, obliterating the musculi pectinati almost entirely, and so converting the auricle into an uncontractile sac: thus furthering mitral regurgitation, and, by its undoubted effect of congesting the lungs and brain according to the auricle affected, mainly producing the frightful dyspnœa and brain symptoms which constitute the worst features of the malady.

Of what value is the nitrate of potash in large doses in *acute rheumatism*? I have had no experience of it myself in *acute* rheumatism, trusting as I have done to calomel, opium, Dover's powder, antimony, and, in the worst cases, bleeding; but my friend Dr. Fenwick of North Shields, who afforded me valuable assistance in preparing the first series of the above cases, when clinical clerk in this house some years ago, as did also Mr. Gibb, informs me that he has adopted it to a large extent in private practice in Shields, and has found it to answer in a remarkable manner. I would also refer you to Dr. Basham's cases of the acute form, and his treatment by the nitrate of potash in large doses,—a paper read to the Royal Medical and Chirurgical Society of London. His success was great, the urine acquiring a high specific gravity, and the salt being detected in it. The specific gravity was raised to 1030 and 1040, which he thinks was owing to the nitrate, though Dr. C. B. Williams attributes it to the urea and the lithates which are by its agency made to be present in the urine. Dr. Basham states his belief that, owing to its agency in acute rheumatism, there is a certain degree of *exemption* from disease of the heart.

I will conclude this paper (already too long) by recording certain facts and deductions which have manifested themselves to me from the careful investigation I made of the above cases.

In 9 cases out of those wherein no relief or only slight relief was obtained, there were either *purulent collections* somewhere, or the usual *common inflammations* which precede suppuration—such as testitis, obstinate conjunctivitis, erysipelas. Are we entitled to deduce from this the general therapeutic principle, that in chronic rheumatism, when it is in that aggravated form in which we have pus circulating in the blood, the treatment by nitrate of potash is not to be depended on, and must be relinquished for another?

Again, in 81 out of the 100, the cure was almost or altogether effected in fourteen days by the nitrate of potash in large doses, and these were cases wherein, though severe, there was no suppuration, nor ordinary inflammation of particular organs. It has been before laid down that nitrate of potash acts primarily on the nervous system. May we not infer, then, that those 81 cases were cases in which the nervous system was alone at fault? And from the two considerations taken together, may we not look at rheumatism as a disease composed of two varieties—viz., that in which its assaults are expended on the nervous system alone, and that other more severe one in which pus circulates in the blood? Various observations and reflections have led me to take this view of the subject. Rheumatism is first a nervous and then a blood disease, and it maintains a distinct individuality in both these phases in a manner more singular than other complaints.* In what I call its nervous form it is a kind of Harlequin inflammation, and less mischievous than it seems. A little energy will knock it out of the system: if uncontrolled, it undergoes a transmutation, becomes grave, enters the blood, and changes it, and walks into the heart itself, the citadel of life. At present we want a set of careful microscopic experiments on the blood in all the varied conditions of rheumatism. Last year, at my request, Mr. Gibb took for microscopic examination small portions of the blood of several patients affected with different diseases. In the blood of one who had no trace of inflammatory affection of any kind we found, to our surprise, numbers of pus globules. In a few days there was developed in this patient a severe erysipelas, which finished by becoming phlegmonous. Here, then, inflammatory disease existed in the blood for a certain time without betraying its presence, until at length its increase became such *(vires acquirit eundo)* that nothing but an acute attack upon the skin sufficed for its elimination.

3. In cases wherein *mercury* has been previously extensively taken, and in cases where there is syphilitic malady

* Look at its remarkably migratory character, its sudden metastases, its lightning-like transitions from one membrane or muscle to others in remote parts! They present no analogy to any ordinary inflammation, but rather to certain phenomena seated at the extremities of the nervous system—urticaria, ambulent erysipelas, erythema, chorea. Dr. Hughes declares that, next to fright, rheumatism is the most common cause of chorea (14 per cent.); and frequent occurrence of spasmodic affection with pericarditis, which is rheumatic, has been particularly illustrated by Dr. Bright and Dr. Burrows.

present in the system, whether mercury has been taken or not, the nitrate of potash is without power. The remedy is the *hydriodate* of potash.

4. In cases of general chronic rheumatism, in which *sciatica* is the most painful feature, the nitrate of potash will banish the complaint from the other parts, but will not avail against the sciatica. In this event, *arsenic*, where it is borne, is the most powerful remedy.

5. In cases wherein the symptoms are doubtful, being circumscribed though severe, and simulating such other common inflammations as pleuritis, peritonitis, ordinary cerebral or spinal meningitis, and even spinal irritation and hysteria, the *state of the tongue*, if it appear as if overlaid with a coat of deep or light white paint, so constant in the rheumatic condition, will most essentially guide the diagnosis.—*Medical Gazette.*

CURE OF FISTULA BY CAUSTICS.

By H. B. Evans, Esq., M.R.C.S.

In October, 1850, W. E——, box-maker, aged 42, applied to me with an abscess in the neighbourhood of the rectum, pointing externally, which was opened, and gave exit to a large quantity of pus. This gradually degenerated into a deep fistulous tract along the rectum, and communicating with it at its extremity. For two months the usual remedies were adopted without success, and I then expressed my opinion that an operation must be resorted to. In this I was fully borne out by the opinion of an eminent hospital surgeon whom I called in. This the patient obstinately refused to submit to, and such refusal led to my adopting the mode of treatment I am about to detail.

A blunt-pointed silver probe, five inches in length (the sinus itself being four inches in depth), was inserted into the wound, having previously been dipped in dilute nitric acid (one part of acid to one part of water), and suffered to remain there a minute. That this had a strong cauterizing effect, I knew from the pain it occasioned. Thus far the result was desirable; but in consequence of the destruction of the silver probes by the acid, and the impossibility of using them more than three or four times, I had some copper ones made, and used them in the same manner, only thus substituting a nitrate of copper for a nitrate of silver, and I think with a better effect. Under this treatment I was pleased to see the depth of the sinus daily decrease by the gradual filling of it up with healthy granulations from the bottom. This was continued nearly every day for two months, February 22, 1851, being the last occasion on which I thought it necessary to apply the nitrate of copper. The patient is at the present time perfectly sound.

In March, 1851, W. H——, aged 30, applied to me with strumous disease of the testicle. Iodine and iron were given, which arrested the progress of the disease, and produced a corresponding improvement in his health. The outward form of the testicle was retained, but with an open sinus of an inch and a half in length in an oblique direction from the apex, and discharging a thin, white, glairy fluid, peculiar to fistulæ. The same treatment was pursued as in the former case, the sinus becoming entirely filled up, and the patient discharged at the commencement of the present month (September), without any external marks of previous disease, beyond a slight irregularity on the surface and a small cicatrix.

Thus by an easy method may the most strumous fistulæ be traced to their extremities, and a strong caustic power applied to the bottom of the wound, from whence it is so desirable granulations should arise.

A limited sphere of private practice enables me only to give these two cases; but I have no hesitation in saying, that if this system be approved of and practised by surgeons generally, they would have as much reason to be satisfied with it as myself and patients, and the use of the knife would become almost obsolete. When a silver and copper wire are introduced together, after having been dipped in the acid, the caustic effect is intense (likened by the patient to a red-hot wire), and if allowed to remain too long, would destroy the tissues with which they were in contact. This, I apprehend, is the effect of the galvanic action set up by the contact of the copper and silver wire with the acid acting upon them.

Before concluding, I will just observe that the treatment in the first case was put into practice some time before the report of the treatment of "Fistula and Hæmorrhoids by Platinum Wire made red hot by Galvanic Battery, by Mr. Marshall, of University College Hospital."—*Mr. Evans of Blackfriar's road in Lancet.*

HOT WATER IN SPRAINS.

By S. Jackson, M.D.

The immediate application of cold water in sprains is strongly recommended by M. Baudens in a previous number of your journal, and as my practice for the last thirty-four years has been the very opposite of this, and has yet led to equally desirable results, I beg leave to relate it on the present favourable occasion.

I was riding past the house of one of my patients thirty-four years ago, and heard the screams of anguish: a woman had just sprained her ankle, and was then suffering intensely. I ordered the foot to be put into water as hot as she could bear it, and to be retained there until I should return; hot water to be added as the first became cool. In about an hour I found that the pain had diminished almost from the very first minute, and that it was then entirely gone. She was put to bed with the foot greatly elevated, and after some hours, though there was no pain, towels dipped in cold water were freely applied, and continued for several days. She was then perfectly well, nor did she ever again suffer from that sprain.

Another strong case within my clear recollection is the following. A man sprained his ankle, and suffered such severity of pain as to make him cry out most lustily. I was present in a few minutes, and put his foot into hot water, immediately bleeding him largely from the arm as he sat in his chair bathing his foot. The pain became rapidly milder, and I went into the next room to drink some tea. Looking over my shoulder after a few minutes, I saw his friends employed in fanning him and sprinkling his face with cold water. I ran to him, when, to my horror, he was, as to human eyes, a mere corpse. I instantly tilted his chair, laying him flat on his back, and ordered them to elevate his legs. Cold sprinkling and spirits of ammonia were most diligently used, but it was an alarming time before he was restored. He was now put to bed entirely free from pain, and the next day he pursued his journey in the stage without any inconvenience, having a flannel bandage applied.

This man told me he had no idiosyncrasy with respect to losing blood; he was large, vigorous, and healthy; hence the bleeding did not produce this alarming crisis. It was, in a great measure, the flaccidity of the body and mind, effected by a sudden transition from extreme suffering to perfect ease; though it must be apparent that the bleeding and bathing worked together so powerfully as to require more careful watching in any future case.

I once suffered a violent contusion of my elbow, followed by intense pain. The arm was immediately put into a tub of hot water, when it soon became entirely easy, requiring nothing further except rest. I have treated many other sprains and contusions in this way, and I do not recollect a single case wherein the hot water failed of giving surprising relief.

I had been prepared for trying this method by reflections on the great comfort of warm bathing in many cases of conjunctivitis, before any considerable *error loci* had yet been formed; and on the fact, that in general relaxation of the system there is less pain from parturition or any other violence.

How long that state of the part which is benefited by hot water may generally continue after the accident, can hardly be defined. I have no recollection of using this remedy after a lapse of two hours, but I cannot be prepared of course to define the limits. If there has been

time for inflammation to form, heat is inadmissible on my principle. Sometimes a tumour will instantly rise, but this being without inflammation, there can be no objection to the hot water.

It is very desirable to ascertain the best methods of refrigeration. M. Baudens keeps the foot night and day in a tub of cold water—a very inappropriate and inconvenient practice, if I am not greatly mistaken; for it prevents the proper position of the limb, which ought to be much elevated, and evenly so, from the acetabulum to the foot. Towels dipped in ice water, and spread over the limb, and bladders of snow or of pounded ice, so placed that their weight may be supported by the pillows, are very conveniently applied. Ice or snow is particularly useful through the night when nurses and patients are sleepy, and heat is sure to accumulate. A certain medium, however, must be observed with respect to the degree of cold, for it may easily be overdone unless the heat be great.

Suppose, then, a violent sprain has been relieved of all pain by hot water, let no one look upon the danger as past. The patient ought to be placed in bed, with his foot greatly elevated, and after a few hours, cold ought to be applied even if the part is entirely easy. Inflammation may form, let us then prevent what every one knows is hard to cure in such parts. I have often seen lead water used, and Mr. B. Bell has confidence in this and natural mineral waters, but truly I cannot believe they have any superiority over the pure fluid.

Low diet from the very first must be used in every case, and purging too, when the system will bear it; but if the patient is robust, he should lose blood from the arm. So much for the prevention of inflammation. I should not say a word about its cure had not M. Baudens advanced something bordering on novelty. He seems to have a horror of leeches because they may attract blood to the part. Now if the general arterial action has been lowered, and the leg kept elevated, this horror need not be entertained. This, I think, will be the decision of a great majority of the profession in the present case. If I were called to a sprained ankle already in a state of severe inflammation, I should certainly, after bleeding from the arm if necessary, apply an abundance of leeches, and follow them up by cold, the limb being greatly elevated. Mr. B. Bell says, "No remedies I have ever employed answer so well as local bleeding." And in the same page he further says, "When the injury has been severe, we are obliged to apply leeches once and again. They require, indeed, to be repeated from time to time as long as any serious degree of pain continues."

After an indefinite time, when all tendency to active spreading inflammation has been subdued, and the little that is left is very feeble, or confined to a small space, a very active large blister will generally absorb and carry it forthwith out of the body; but this is a perilous experiment, and may do much harm if it do not fulfil our intention of extinguishing at once the whole disease, or of subduing it so far as to prevent reaction, and thus to favour the operation of a second blistering. Whenever it has been determined to use this remedy, the part ought to be rubbed for fifteen minutes with decoct. canthar. ex terebinth., and an active plaster applied, so as to draw an effectual blister in the shortest time possible. The quick drawing of the blister is a point of the first importance in cases wherein you hope to absorb and carry off the whole disease. A slow blister is worse than none; it is sure to irritate and increase the disease, as sinapisms are known to do in similar cases. You are taken with pleurisy or peritonitis: some physicians would apply mustard with the hope of discussing a disease that is yet mild; but, *væ vobis*, you must lose more blood on account of the mustard, and resort to a blister in the end. The best dressing by far for the first few days, is plaintain or cabbage leaves; but if the blister promise to run freely and not inflame, it may be soon dressed with mezereon or savin cerate, and if a copious discharge of pus be obtained, the disease will rapidly pass away. I can never forget the delighted countenance and applauding language of an old physician to whom I showed, in my first year's practice, an ankle in this very condition. He had never known this use of savin, but from that day he used it freely and praised it highly. I had learned it from Crowther's work on White Swellings.

Beware of warm poultices in the dressing of these blisters; for, as M. Baudens rightly says, "they favour in place of opposing the afflux of fluids to the part." And speaking of the long application of warm cataplasms, he says "the long maceration the joint has been submitted to, deprives it of its elasticity, gives rise to a pasty engorgement and predisposes to the formation of white swelling." If it is determined not to use savin, the blister should be healed by the mildest dressings, so that another may be soon drawn; thus the blistering may be conducted without any injurious irritation, and made to absorb gradually and carry off gently all the remaining inflammation. Dr. Rush used to talk and lecture much on his blistering point; and truly no idea or language can be more appropriate. The inflammation must be brought down to a low grade of action, or to a small periphery, so that a suitable blister will extinguish it at once, or so greatly diminish it that one or more subsequent blisters may be drawn with safety and success.

We have already entered our caveat against warm poultices in the dressing of blisters for sprains, and have approved of M. Baudens' doctrine with respect to them; and lest any one should retort that our hot water may have the same bad effect, we must remind him that we explode warmth *after inflammation is formed*. You may bathe a healthy limb in hot water for twenty-four hours and no engorgement will follow. I have bathed a great many sprained joints in the hottest water that could be borne, without any of this evil. It is pain and inflammation that induce this engorgement, and these being both prevented by the hot bathing, this dreaded evil is prevented of course. But let this engorgement accrue, and it will be greatly increased by much heat in any form. Yet there may be old cases in which hot water or steam may appear to revivify the torpid parts and render them sensible to curative means. But suppose you are called to an old case of this leucophlegmatic torpidity, is there a better remedy than frequent blistering that discharges freely? Mr. B. Bell recommends the pouring of warm Bath or Buxton water on these engorged and torpid joints, but there is far more vivacity in the operation of cantharides, and the discharge not only carries off the evil stimulation, but it empties the vessels and promotes absorption.

In nearly all cases of external violence which do not implicate any of the viscera, the immediate use of hot water is, as I sincerely believe, the best, as it is the surest cure and preventive of pain. If you are about to have a tooth extracted, hold hot water in your mouth both before and after the operation; if you must have a felon lanced, hold the hand in hot water for a long time both before and after the cutting." My first case of what is vulgarly called "inverted toe nail," occurred to me after the patient had thoroughly relaxed the part by warm poulticing for many days, and I did not proceed to the operation of splitting the nail and eradicating the offending portion, till he had bathed his foot a long time in hot water. I had been taught in Dorsey's Surgery that it was a most painful operation, and I was therefore surprised, notwithstanding my hopes from the relaxation, to find the young man making very little complaint. I have several times performed this operation, and owing, as I believe, to the hot bathing, I have not found it severe in a single case. Now, if I am not mistaken, some reader will here exclaim that even in inflammation warm water agrees with some persons and cold with others. This fact, however, I learned when a student from Mr. S. Cooper's prize essay on Diseases of the Joints; but however true this may be, I have not found a single case of bruise or strain in which hot water, when used in time, was not a great present comfort and permanent benefit.—*Amer. Jr. of Med. Sci.*

ON ARTHRITIC HEADACHE.

By William Harvey, Esq.,
Surgeon to the Royal Dispensary for Diseases of the Ear.

In my former papers on rheumatic inflammation of the ear, I observed that the headache and distressing noises succeeded as a consequence of the attack on that organ. In the arthritic variety, however, this is not the case, the head becomes affected for some time prior to its manifesting any disturbance in the ear, and as the symptoms are often very much mistaken, I have thought it essentially necessary to direct attention to their early character; I shall have occasion, however, to allude to some cases which will immediately follow this paper, wherein the ear becomes the seat of mischief from the first. The noises and benumbed sensation of the head, accompanied with intermittent hemicrania, neuralgia of the facial nerves, pains affecting the eyeballs, the ears, the fauces, the teeth, and the lumbar regions, are all premonitory of this diseased condition. I have, in some instances, witnessed for days, the tonsils so sharply seized with gout, as in the absence of any considerable degree of inflammation and careful history, to question for a time the fact; it sooner or later, however, is explained by a seizure of gout, which solves the mystery. When it attacks the ear, the lobe is generally the part, becoming swollen, intensely red, and exquisitely painful, lasting for days and sometimes weeks, attended with deep and distressing noises, referred to the interior of the head. Dr. Holland observes, that it is somewhat difficult to class the several forms of intermittent headache with other affections of this kind, but those having lengthened periods of intermission, may perhaps best be noted here. The equality of time often observed, even where the intervals extend to two or three weeks, or yet longer, is a very remarkable feature in these cases, and denotes a cause, specific in its nature and uniform in its operation. I know instances where such intermittent headaches have occurred during the greater part of a protracted life; more frequently, however, it happens that they affect especially certain periods of life, in this, as in many other circumstances, showing singular relation to various disordered actions of the gouty constitution. In conformity with the same relation, there is reason to believe that the kidneys are the excretory organ most concerned in giving relief in these cases, and principally by an increased separation of lithic acid, or its salts. Such action may readily escape notice where the attention is directed by the presence of pain to another part, but I infer it on close observation of many intermittent headaches, and think the remark likely to be confirmed by others.

Gouty affections of the head constitute one of the most dangerous and most formidable varieties of disease, dependent on or caused by arthritic diathesis. Gout in the head, as it is popularly termed, may be met with either in the form of arthritic headache, or of arthritic apoplexy. The former, indeed, is often the precursor of the latter, and not unfrequently, when it has been mistaken and consequently maltreated, ends in it.

Arthritic headache is a disease that often escapes detection, especially if the patient has not previously had a paroxysm of gout in its regular form, so as to aid the judgment of the practitioner in forming a diagnosis. The symptoms which mark the disease are attributed to an ordinary determination of blood to the head, or rather to the brain, and the treatment is in accordance with such views. A greater mistake could hardly be committed, for all depletory measures in the treatment of gouty affections of the brain and its membranes are injurious, yet such constitute the principal remedies employed to relieve the consequences of determination of blood to the brain. As it is very generally, although not always, that the head, and subsequently the ear, become affected by the metastatic action of gout, I cannot better allude to the subject as a confirmation of my own views, than by quoting the forcible and clear description given of it by Dr. Gairdner. He observes:—"That metastasis to the head appears by far the most usual of misplaced gout. It occurs with every degree of suffering. The headaches from which those persons suffer, in whom the excretions of urates and urea have, from any cause, been suddenly diminished or temporarily arrested, are only a commencement of this affection, which may well be likened to the effect of a poison. I believe that the substance of the brain itself is the part usually affected in these cases, and my reasons are, that they are never attended with delirium or wandering, but always accompanied by stupor or apoplexy, the ruptured vessel is found in the cerebral substance. It has been said that such cases are to be treated like apoplexy from any other cause. I am quite satisfied that this information is most dangerous. Patients affected with gout in the head do not bear the abstraction of large quantities of blood. Much regard must be had to the heart, which is always more or less diseased, and sometimes in an advanced state of disorganization. We may easily and quickly relieve the worst head symptoms; but if the relief afforded be not meted out with wariness and skill, we shall too surely discover that we have fastened on our patient worse and more hopeless evils. The abstraction of much blood is, however, wholly unnecessary. A relief given to the system by a small bleeding will enable the kidneys to resume their office, and the worst symptoms will then safely depart."

In these cases colchicum is a most useful remedy. I have mentioned the discovery of Chelius, Maclagan, and Servius, that it greatly increases the secretion of urea. The application of this fact to the case in hand, must be obvious to all, and the effects of the medicine will fully answer their expectation; but here, too, I would insist on the propriety of using minute doses of the remedy, which more safely and not less effectually, than larger ones, accomplish the objects in view. Laxatives in head cases are always necessary; and even drastic purgatives may be required. Prudence, however, is indispensable in their use; for while no constipation is permitted which would urge the blood to the head, regard must be had to the patient's shattered condition. Precise rules cannot be laid down; but the experienced physician will hardly err, if he do not lose sight of the impaired condition of the circulation, at present labouring under a double disadvantage from the oppressed state of the brain, in addition to disease of the central organ."

Arthritic headache, then, is a disease which demands considerable discrimination and close observation to detect, based on the information obtained by extensive experience, as it is only by distinctive signs, which, by some may be regarded as apparently trivial, that we shall be enabled to determine the true nature of the attack. It occurs generally among those in whom gout fails to show itself in the ordinary way, but remains lurking in the system ready to pounce upon any organ which, by fortuitous circumstances, may be liable to take on diseased action. The higher classes of the community, among whom gout is frequently an heir-loom being in many instances transmitted by both parents, are far more liable to this form of metastatic gout than are either the members of the middle or of the lower orders of society. It is, likewise, found more readily to affect the females of a gouty family than the males, and more frequently after certain periods of life have been reached. The younger members, and the male branches, do not meet with absolute immunity from arthritic headaches, but they are much less subject to attacks. The symptoms which are not pathognomonic of this disease are—a sense of fulness in the head, generally constant, but liable occasionally, from casual circumstances, to change into severe pain; a feeling of vertigo or giddiness, and if a movement were occurring in the head—a feeling to which the attention of the patient is continually drawn, and which, apparently, impairs the power of thought and of memory; all the perceptions are confused, and the patient at the same time experiences a sensation as if he were about to become insensible. If he stoops, he is apt to be seized with temporary blindness, the hearing is inordinately acute, the

least noise rendering him almost distracted; he is frequently troubled with a buzzing sound, and sometimes with other noises in the ears; flushings and heat pass at times over the head and face; the hair is often tender and painful when touched, and the scalp feels hot, constricted, and uneasy. With respect to the general symptoms which attend upon this state, they are such as indicate a disordered condition of the digestive apparatus, and an ill-regulated and badly-formed secretion.

The function of digestion is most frequently very imperfectly performed; flatulence, with acid eructations; a sense of weight and general uneasiness at the pit of the stomach; rumbling in the bowels; an unpleasant acid or bitter taste in the mouth; the tongue furred with a brown fur, with occasional yellow streaks; a disordered state of the bowels, which are sometimes confined and at others much relaxed, the stools being generally clay-coloured, showing a deficiency of bile, or else very high-coloured, dark, and offensive, showing a redundancy of that excretion, but in a very unhealthy state; the urine unusually scanty, and high-coloured, and depositing a reddish sediment on standing, with a rough dry skin, are symptoms which indicate a general disarrangement, and an imperfect performance of the ordinary functions of the body, by which the effete matter of the frame is got rid of by means of the secretions and excretions, and fresh pabulum or material furnished to supply the waste of the system. Meanwhile, in the midst of much disorder of the secretive apparatus, the pulse generally remains undisturbed, or, if at all altered, shows a diminished rate of circulation, a lessened degree of tone in the system.

The symptoms are those that are found to be placed almost beyond the possibility of a doubt. It is the result, I conceive, of a morbid condition in the function of sanguification, or perhaps of the immediate preparatory process or chylification, by a failure on the part of the kidneys to perform rightly their secerning duties, by which the separation of urea and uric acid upon the blood should be effected. The presence of this acid in the circulating medium, then, may be regarded as characteristic of the gout, and the fact ascertained by Chelius of Heidelburgh, that in the course of twelve days, under the administration of colchicum, the kidneys are excited to abstract from the blood nearly double the quantity of uric acid they had previously separated, will amply serve to explain the remedial influence of colchicum in the relief of the disease, and the manner in which the influence is excited.—*Prov. Jr.*

TREATMENT OF UNUNITED FRACTURE BY THE INSERTION OF IVORY PEGS.

By Mr. Stanley at St. Bartholomew's Hospital.

Abraham B——, aged 24, a healthy-looking countryman, employed in the construction of railroads, and not addicted to excessive drinking, was knocked down by a horse two years before his admission. By this accident he suffered a compound fracture of both bones of the right leg, towards the lower third, and the violence was so great that the upper fragment was forced through his Wellington boot. The patient was placed under surgical care at Slough, and the reduction was effected with much trouble, a whole hour of strenuous efforts having been necessary for accomplishing it. The limb was put up in splints for two months, and in Simpson's patent apparatus for four months, but no union took place, though the wound had readily healed.

The patient now left the hospital to recruit his health in the country; he contrived to do light work in Devonshire, with pseudarthrosis of the leg; and succeeded in lessening the inconvenience of this state of things by making for himself an apparatus composed of iron hoops and a connecting rod. Thus he went on for eighteen months, and was finally advised to apply to Mr. Stanley, under whose care he was admitted October 7, 1850, two years having elapsed since the time of the accident.

On examination, the fractured portion of the limb allowed of extensive motion, a false joint had been formed, and the patient stated that he felt a grating at every step he took. Mr. Stanley first tried blisters for a month, then splints and various other contrivances (among which was a casing formed of gum and chalk) for keeping the fragments in apposition; but these were of no avail, and union did not take place. The patient now returned into the country, and after a short stay, during which his general health improved, he was readmitted.

On Feb. 16, 1851, Mr. Stanley decided upon driving ivory pegs into the extremities of the fragments, according to Dieffenbach's method. The patient was placed under the influence of chloroform, and a flap of integument over the fracture having been reflected, Mr. Stanley bored four holes with an instrument of the class of drills made for the purpose, two on the upper, and two on the lower fragment. Into these holes four ivory pegs were inserted, or rather hammered, with nearly a quarter of an inch of the peg remaining over the surface of the bone. The flap of integument was then replaced, and the patient's leg put into a fracture-box.

Inflammation ran tolerably high, suppuration was soon established, without constitutional disturbance, and the pain was very trifling. Three days after the operation a small abscess formed on the upper part of the flap; Mr. Stanley opened it, and a fortnight afterwards something was seen projecting from the wound, and when pulled out it proved to be one of the pegs. The flap now cicatrized, and two months after the operation Mr. Stanley proceeded to remove the remaining pegs, the soft parts having been laid open for the purpose. It was found on examination that the portion of the pegs which had been above the bone was quite unattacked, whereas the part which had been embedded in the osseous structure had nearly disappeared.

Mr. Teale of Leeds (who has performed the same operation successfully), has remarked analogous phenomena respecting the unaltered state of the upper part of the pegs, and the almost complete absorption of the part situated within the bone, the whole peg having pretty well the same appearance as the milk tooth of a child with the fangs nearly absorbed.

On May 13th, three months after the introduction of the pegs, the patient had a sharp attack of erysipelas of the leg; this was arrested by the usual remedies, and a circle of nitrate of silver on the upper part of the limb. The fracture was now found to be approaching consolidation; but Mr. Stanley desired the patient not to use his leg for some weeks, and when the latter began to try the limb, about four months after the operation, the fracture was found perfectly united, firm, and immoveable. He continued in the hospital, carefully walking on crutches, for another month, and was discharged in the latter end of July, 1851, with a sound leg, about five months after the operation.

Dieffenbach's method has also been applied by Mr. Bowman, at King's College Hospital, in a case of a very interesting kind. We shall have much pleasure in acquainting our readers with the results as soon as they are of a decided nature.

Before dismissing the subject, we would just mention that acupuncture in cases of ununited fracture has here and there been very successful; and as this measure is not so severe as the *pegs*, we shall quote from the second volume of the Mémoires de la Société de Chirurgie de Paris (1851), a paper by M. Lenoir, of a case of ununited fracture of the femur, in a man aged 33.

The patient had been fifty-three days under treatment at La Pitié, and the callus had then been satisfactorily thrown out; but the surgeon, M. Bérard (1845), desirous of overcoming the stiffness of the knee-joint after the man was already getting up, subjected it to passive motion, and in one of these manœuvres the callus gave way, and henceforth refused to form again.

M. Lenoir saw the patient four months after the accident. He first resorted to rubbing the fragments, starch bandage, and continuous extension; these means yielded

ROYAL DUBLIN SOCIETY

no result after two months' treatment. The author had then recourse to acupuncture, discarding resection of the fragments, the ligature with a metallic thread, and the seton, as too hazardous. The limb was placed in a box, where extension could easily be made. Seven months after the original accident, four needles, four inches in length, were thrust along the internal surface of the superior fragment, and were left six days. Some inflammation was then excited; the needles were withdrawn, put in again a little higher up, and left five days. After this the fragments were approximated, and kept closely connected by little splints placed round the limb, and secured with straps. Extension was made very gently at first, and the surgeon visited his patient *every day* to regulate both the extension and the pressure by the splints.

After twenty-three days some firmness was noticed between the fragments, and in thirty-five days consolidation had taken place. Œdema of the thigh and leg were combated by the proper means for a fortnight; and after careful trials with the crutches, &c., the patient walked out, about six months after the implantation of the needles, with less than an inch shortening.—*Lancet.*

COD-LIVER OIL IN SCROFULOUS AFFECTIONS AND IN CONSUMPTION.

Dr. Hays has stated to the Philadelphia College of Physicians that he had employed the cod-liver oil extensively in the Wills' Hospital and in private practice, during the last three years, in scrofulous ophthalmia, in cases of granular lids, in scrofulous enlargement of the external glands, in cases of hip-disease, and in the various forms of external scrofula, with the best effects. In scrofulous ophthalmia he had found it of all remedies the most efficacious. Under its use the constitution becomes invigorated; the glandular swellings are dissipated; and the cutaneous affection so commonly met with about the face and ears disappears. He has also employed it in several cases of granular lids with the most favourable results. In this affection, patients are very liable to relapse from slight causes; this tendency he has found to be removed by the use of the cod-liver oil alone, or in conjunction with the syrup of the proto-iodide of iron. In the case of a lad now under treatment affected with scrofulous enlargement of the cervical glands, chronic conjunctivitis, and granular lids, with deposit of lymph in the cornea, and intense photophobia, by the use of the cod-liver oil and proto-iodide of iron, with the occasional application to the eye of the liquor plumbi, all the symptoms of disease are rapidly disappearing. The patient can bear the light without inconvenience, can read small print, and has all the general appearance of restored health. He has escaped a relapse now for four months. The photophobia has disappeared entirely. In another case of excessive photophobia, with granular lids and penetrating ulcer of the cornea, the cod-liver oil has been used (at the suggestion of the *interne* of the Wills' Hospital, Dr. Macintyre) with the most decided advantage. Dr. H. has now employed the cod-liver oil in from two hundred to two hundred and fifty cases of scrofulous ophthalmia and granular lids, and in most of these cases the benefit resulting from its use has been very striking.

Dr. Condie remarked that he had employed the cod-liver oil pretty extensively. In all the forms of external scrofula, including scrofulous ophthalmia, he had certainly seen much good result from its use; the indications of strumous disease have very generally ultimately disappeared under its use, while the appetite of the patients has improved, and they have speedily exhibited an increase of strength and bulk. It is especially in the scrofulous affections of young subjects that the cod-liver oil had appeared to him to produce the greatest amount of benefit. He had not, however, seen any very striking amount of good result from its administration in cases in which tuberculous deposits had actually taken place in any of the tissues. In tubercular phthisis especially he had rarely, if ever, observed any positive benefit from its use. He had given it in many cases, and in large quantities, and though it had been taken perseveringly by the patients for a long period of time, he could not say that in a single instance the disease of the lungs had been arrested by it. The onward march of these cases towards a fatal termination appeared to him to be as rapid as those in which the oil had not been given. The wife of a gentleman connected with the public press, now under the care of Dr. C., had used it daily for the last three years, and she believes with very decided advantage. But though in her case the affection in the lungs is of a very chronic character, still the frequent attacks of hæmoptysis to which she is subject, and the physical signs revealed by auscultation, indicate that her disease is making a slow but constant progress.

Dr. Wood had never met with any one remedy or combination of remedies which had proved so efficacious as this in pulmonary phthisis. It is too soon, however, to say that in any case it will permanently cure the disease. He has certainly seen cases presenting, apparently, all the phenomena—the general symptoms as well as the physical signs—characteristic of phthisis, get well under its use. The patients have, at least, lost their cough and fever, their respiration has become natural, and they have acquired strength and flesh. In one case which occurred in hospital, auscultation indicated the existence of a cavity at the summit of one lung, and deficient respiratory murmur in the other. The patient was pale, extremely feeble and emaciated, with hurried respiration, cough, and copious expectoration, hectic fever, and night sweats. Although in this case Dr. W. expected little, even temporary, benefit to result from any plan of treatment, still he thought it his duty to place him under the use of cod-liver oil. At the end of six or eight weeks, he was surprised to see the patient able to sit up, and considerably improved in all respects. From that time the unfavourable symptoms gradually lessened, the cough and expectoration abated, the respiration became more free and easy, the hectic fever and night sweats disappeared, the pulse increased in strength and diminished in frequency; and, at the termination of four months from the commencement of treatment, the patient had become fat, ruddy, strong, and to all appearance, entirely well. Upon an examination of the chest, a deficiency of respiration was detected in the vicinity of that portion of the lung in which a cavity had existed—which is precisely what we should have anticipated. This is the most striking case which he has met with of the cure of pulmonary disease under the use of cod-liver oil.—*Amer. Jr.*

APPEARANCE OF ALBUMINOUS URINE IN DIABETES.

M. Rayer makes this question the subject of some practical remarks in a paper read before the Biological Society of Paris. He alluded to a case which he saw in consultation with M. Landouzy, which had improved, to a certain extent, under the use of alkalies, with abstinence from farinaceous matters, when albumen was detected in the urine. There were, however, no other signs of Bright's disease; and the appearance of albumen was a phenomenon for which M. Rayer had no ready explanation. MM. Dupuytren and Thenaud considered that when albumen appeared in the urine of a diabetic patient it was indicative of improvement, being, as it were, a transition stage between the saccharine state and that of health. M. Rayer, however, is disposed to regard the change as not salutary, as in cases witnessed by him, though the sugar disappeared, the occurrence of œdema showed that the change was not for the better. In fact, in more than one case, although there was no recurrence of sugar, the patient died of one or other of the consequences of albuminuria. A case related by Dr. Christison also proves that the appearance of albumen in the urine may be an indication of a serious complication, to be followed soon by other symptoms of renal disorganization. The case was that of a man aged 40, who had been the subject of diabetes for two years. Unexpectedly it was found that the urine coagulated by heat and nitric acid, and that its specific gravity became lower, until at length it was as low as 1.010, without any traces of sugar being present. The man soon after died from diarrhœa, and after death his kidneys were found in an advanced stage of granulation. It may therefore be taken as a pathological fact, that though in some case the substitutions of albumen for sugar in the urine of diabetics may be a good sign, in others it may indicate a serious complication.

TREATMENT OF DIARRHŒA BY SULPHURIC ACID.

Having used the sulphuric acid pretty freely during the past month, it may not be uninstructive very briefly to record my impression as to the description of cases to which this admirable remedy is more strictly applicable. In Glossop, as well as in many of the manufacturing localities surrounding Manchester, we have had, during the splendid autumnal month just closed, multitudes of hasty cases, to which indiscriminately have been applied the terms "bowel complaint," "English cholera," "diarrhœa," "vomiting and purging," the two latter terms being pretty constantly a correct description of the more prominent symptoms. Few cases have proved fatal; happily, in our practice none; though many aged persons have suffered severely, still recovering from the debility produced by cramp and profuse watery purging more rapidly than could have been anticipated. In several instances of this latter class (seen by my partner, Dr. Hunt, as well as by myself) the acid, to use his own words, has acted "*like a charm,*" and in none have we had recourse to any other remedy,—subduing cramp, restraining vomiting, rousing the pulse, and with it the heat of surface,—supporting, in fact, the whole vital energies, and apparently effecting this by checking profuse watery secretion, and its consequent discharge from the bowels. Mr Griffith has referred to the recommendation of a writer on medical therapeutics, the late Dr. A. T. Thomson, who prescribed the acid in "*passive*" diarrhœa. I conceive such an authority would never have dreamed of its use in cases simulating or closely resembling cholera as seen unmistakably by me, both in India and England. One thing is certain—the acid is inadmissible *where the purging is decidedly dysenteric.* We have then found the ordinary remedies, such as Dover's powder, combined with the "mercury-with chalk," answer better. Another thing is worth recording. It may be given advantageously in freer doses than Mr. Griffith supposes. Our formula is—Half an ounce of the dilute acid of the London Pharmacopœia to seven ounces and a half of water. This may be taken in divided doses of an ounce every two hours, or even more frequently, should the first doses be rejected from the stomach, or purging be frequent. Some cases will undoubtedly give way to opiates; but they leave headache, a foul tongue, and fever. Into the question of the pathology of this affection I will not enter. Your publication is valuable to practitioners precisely in proportion as its contents are *practical.* Hospital reports are necessarily routine cases, and are statistically worth recording; but no man has a right to encumber the pages of a medical periodical with mere theories, or a string of common cases, presenting no peculiarity of practice. I have presented you with the results of the treatment of at least sixty cases, and think the knowledge of the value of the acid (using proper discrimination in the avoidance of inflammatory dysentery) a great and most valuable fact—one forming the material out of which medical weekly serials are best, because most usefully, compounded.—*Mr. J. A. Smith of Glossop, Derbyshire, in Lancet.*

Treatment of Pneumonia.—Dr. Dietl, an Austrian physician, who appears to have been very undecided in his therapeutic principles, has recorded the results of his practice in pneumonia. At one time he was a great advocate for bleeding and the antiphlogistic system, subsequently he turned homœopath, and still later he trusted to tartar emetic. Being dissatisfied with the mortality under each of these plans, he determined to abide by the *methode expectante*, or do-nothing system, and he declares that the recoveries have been more numerous than when he treated his patients medicinally! He gives the following statistics, which are so far valuable, inasmuch as they show that homœopathy and doing nothing are convertible terms:—

Of 360 cases of pneumonia, 85 were treated by bleeding, with 17 deaths, or 20 per cent.

Of 106 healed by tartar emetic, without bleeding, 22 died.

Of 189 treated by a purely expectant method, 14 only died.

The mortality under homœopathic treatment was the same as when no medicine at all was given.—*Prov. Jour.*

REVIEWS AND NOTICES OF BOOKS.

PRACTICAL OBSERVATIONS ON THE TREATMENT OF STRICTURE OF THE URETHRA AND FISTULA IN PERINEO; illustrated with Cases and Drawings. By John Lizars, late Professor of Surgery to the Royal College of Surgeons, and Senior Operating Surgeon to the Royal Infirmary of Edinburgh. 2nd edit. Edinburgh. 1851. 8vo. pp. 130.

We had occasion very recently, in reviewing Mr. Lizars' and Mr. Syme's works on Stricture, to notice the mode of treatment by external incision, as practised and recommended by the latter in cases of obstinate stricture, and to call attention to the conflicting statements respecting the efficacy of this operation in permanently relieving the disease. While Mr. Syme asserts that it is a simple, safe, and certain mode of relieving stricture, Mr. Lizars brings forward proofs that it is neither the one nor the other—in fact, that it is frequently followed by disagreeable consequences, sometimes even by death, and that the patient may not, after having undergone the hazard and pain attending the operation, be relieved of his complaint.

The interest which the question has excited is evidenced by the rapid sale of the first edition of Mr. Lizars' work—a new edition (that before us) having been called for within a few months from the publication of the first. In this edition the letterpress of the preceding is preserved, the new matter being added in the form of an appendix, while two additional engravings are given.

This appendix commences with the following short outline of a case where fatal hæmorrhage occurred after the operation by external incision:—

"Captain Mc——, from Fifeshire, had laboured under stricture of the urethra for some years, and along with his ordinary medical attendant, came to Edinburgh for a consultation, which was held with a perineal sectionist. An operation was recommended, as might be expected, by the latter. The family surgeon advised the patient to let 'well alone,' as a fair sized catheter could be passed through the stricture, and to trust to the usual mode of obtaining relief. Notwithstanding this counter advice, an operation was performed, and in the course of eight days from the time the Captain left his home, according to the surgeon's report, from whom I obtained the preceding particulars, he was brought back to his mansion a corpse. His wife, who remained in attendance upon her husband in Edinburgh, stated that he died from flooding on the second or third day after the operation."

Mr. Lizars next quotes some of the numerous communications which have appeared in the periodical press respecting Mr. Syme's operation; among them are several letters from Mr. Gay, with Mr. Syme's replies, followed by extracts from the *Medical Times* and from the *Edinburgh Monthly Journal* upon the same subject. Professor Miller's remarks upon the treatment of stricture by external incision are then quoted; in which a fatal case after the operation, and another showing the risks arising from it, are recorded. The following are the author's comments upon Professor Miller's communication:—

"Professor Miller's remarks on the treatment of the perineal section corroborate, generally, the opinion which I expressed in October last, when I published the four cases whose histories have drawn, to no inconsiderable degree, the attention of the profession to this important subject. I characterized, at that time, the operation as uncalled for; as a painful, hazardous, and unsuccessful experiment. Subsequent events, both here and in London, a more searching inquiry, and minute exposition of facts, and the results of attesting experience, have all contributed to confirm these statements.

Professor Miller has added *another fatal case*, making, with *the two* cases contained in my appendices, and the other *three* in Mr. Gay's table, with one in 1829, not less than *seven ascertained instances of death succeeding to and occasioned by the operation.* So far, therefore, as it is a hazardous operation, no doubt can be entertained, and farther proof is unnecessary. . . . . .

Professor Miller has given the history of a case illustrating the great and many risks arising from the operation, although this case was operated on by Mr. Syme in January, 1850, and although since that period he has published a variety of cases, *immediately* after the operation, to fortify its value, he has never thought proper to *print* one word of this case, on the pretext which he assumes for publishing other cases, 'as containing information that may interest the reader.' "

The remainder of the volume is occupied with extracts from a correspondence between Professors Miller and Syme, which appeared in the *Edinburgh Monthly Journal*, into which however we shall not enter; and it concludes with some extracts from Mr. Courtenay's work on stricture of the urethra, which might have been omitted without detracting from the value of the essay. We shall conclude by quoting Mr. Lizars' concluding remarks:—

"I have engaged in this controversy, conscious of being actuated solely by a desire for the discovery of truth, and that reflection has enabled me to submit, without retaliation, to much injurious misrepresentation, and I shall consider my labours neither misapplied nor unrewarded, if they have the effect of restoring confidence to the old and safe practice of treating stricture, and of averting an uncalled for infliction of human suffering, by arresting the progress of an innovation rashly resorted to, and indiscriminately persisted in, in opposition to all argument, and in defiance of all warning."

STUDENTS' NUMBER OF THE MEDICAL PRESS.

THE STUDENTS' NUMBER will be published on WEDNESDAY, the 29th of OCTOBER. Regulations of Universities, Colleges, and other Institutions for Medical and Surgical Education, properly authenticated, should be transmitted to our Office *without delay*, in order to secure a proper and careful analysis of them. Advertisements of Lectures and Hospitals, Books, Surgical Instruments, and Medicines, should be forwarded in sufficient time to secure a proper arrangement of them.

DUBLIN: WEDNESDAY, OCTOBER 22, 1851.

MEDICAL EDUCATION.

THE GRINDING SYSTEM.

WE could not for the life of us refrain from giving publicity in Ireland to the following graphic sketch of the manufacture of the medical paddle-wheel of the "General Practitioner" craft at the other side of the water. It tells so much, explains so much, and suggests so much, that to consign it to oblivion would be a sin, From it we gather that the letters L.A.C., are not much more trustworthy symbols of contents than M.D., and that our worthy brother John is just about as perfect as his neighbours, notwithstanding his pleasing convictions to the contrary. If we in Ireland suffer from this "Grinding System," it is a comfort to find other places in the same predicament; and if the evil be such a crying one, there is a much better chance of its cure when it prevails extensively, than if it was confined to a more limited sphere:—

THE LONDON GRINDING SYSTEM THE GRAND OBSTACLE TO SOUND MEDICAL ACQUIREMENTS.

(A Letter to the Editor of the Medical Gazette.)

SIR,—I perceive in one of the leaders of your last week's journal, an account of some late resolutions of the Court of Examiners of the Company of Apothecaries, having reference to the preliminary education of students intending to qualify themselves at the Hall.

On these resolutions, and on other subjects connected with them, I should like to offer some observations if you will kindly allow me the space necessary.

You observe, sir, that this act of the Apothecaries' Company "is a step in the right direction," and with this opinion I of course cordially agree; but at the same time I must protest, that the step is the shortest possible step, and but a mole-heap, compared to the mountain of improvement that requires to be raised.

The examiners affirm "that the great obstacle to the acquirement of sound medical knowledge is the general want of preliminary education among the pupils, and that until this serious defect is removed, the progress of medical science will be retarded." Now, sir, although I willingly admit that a liberal preliminary education is a good thing, and that the above declaration of the hall examiners has a certain foundation in fact, I cannot admit that the deficiency assumed has had much to do with the retardation of sound professional knowledge amongst young medical men; I am rather convinced that the method pursued by most students in obtaining the information necessary to pass the hall is such as to render their medical acquirements too deceptive for examiners to come to any certain conclusions on the matter.

The cause of this deception rests in the prevalence of that most iniquitous practice, *the London grinding system*, and the success of this system rests mainly upon the errors of the examining court itself.

In the pages of your journal for April 19th, 1844, there appeared, sir, a bold and admirably written leader, in which the grinding system as it then existed was fully exposed, its iniquity laid bare, and the causes of its success explained. That leader I chanced to read some months ago, and thinking it might not be unimportant to ascertain thoroughly what was the extent of the grinding system in these days, I have made it a point ever since to inquire into the matter, with intent always of exhibiting this monstrous fraud to boards of examiners and to the world at large. The present declaration of the Apothecaries' Company affords me an opportunity of carrying out my purpose.

And, at the outset, I would observe that since the date of the leader referred to (1844), the grinding system instead of falling into disgrace, has gone on, in a steadily progressive manner, that it is now more perfectly organized than ever, and never was practised more successfully than at the present hour.

The writer of 1844 speaks of a certain grinder, who so excelled in his art "that he knew to a nicety when each of the subjects who committed themselves to his care was in a fit state for presentation; just as the feeders of geese at Strasburg know to a tittle when each animal's liver is in proper state to be made an element in the celebrated *paté de fois gras*." But the profession of grinding then practised only by one or two, has been found so lucrative that at the present time at least half a dozen professors live by this most iniquitous use of their acquirements. At the period already named, the knowledge of the grinder as to the kind of information which the student must have, seems to have been very great, "he even knew the proper answer for each examiner;" at the present moment, knowledge in this direction is, if possible, still more perfect. To use the common and very expressive phrase, "these examiners are all gauged; the peculiar mode of questioning used by each is known; the subjects on which he usually examines are familiar, and in many instances the very questions as they will be asked, *verbatim et literatim*, with the proper answers required, are indicated. "Gentlemen," says one of the most successful of these crammers in addressing his class, "allow me to drill you well on the ointments, for with Mr. So-and-so for an examiner you might find this a plucking subject."

The most remarkable names are also given to the examiners, to fix more firmly in the mind of the pupil their several peculiarities. Thus one gentleman is famous for examining on the blood, and receives in consequence no very polite cognomen. "Gentlemen," cries the grinder, "with Mr. So-and-so the blood is a plucking subject: you must know the blood. He will commence with mastication, and drag you through all the process of blood-making, according to his own crotchets: above all things, therefore (if he is your examiner), declare to him that the saliva is of great importance, that pepsin is invaluable, and that the thoracic duct is the only channel by which the prepared food gets into circulation. Remember these points, gentlemen, I pray you; and particularly remember the pepsin!"

Again, if a new subject be started at some sitting of the court, the innovation on the routine of the grinder is immediately noted, and forthwith he is fortified on this as well as on all other ordinary subjects. This fact was ludicrously exemplified a little more than a year ago. The illustrious

Liebig had announced a new test for prussic acid; this test was made the subject of a question at an examination in the University of London, and one night an examiner at the hall, in humble imitation, poured it on to the quivering tympanum of an unhappy student. The following morning saw the large grinding class in which this young gentleman had *studied* in a state of unutterable consternation lest the beaten track was to be abandoned, and the cramming they had undergone to be of no avail. But the chief of the grinding class now appeared, and soon threw brightness about him like a sunbeam. "Gentlemen," he exclaimed, "this is indeed something new; but never fear! Those examiners, I assure you, are no match for me; wherever they go I can follow; and what is more, *I can drag you along with me.* Here is the test fully described for you; write it down word for word as I say it, and let every one of you repeat it at least twice daily until such time as you go up, for it is a fresh subject, and is sure to have a considerable run."

If a new examiner is appointed, he is at once made the subject of particular observation, and his line of action ascertained. First, it is learned whether he follows any particular branch of the profession, or has written on any particular subject, and if so, this is put down as being likely to influence him at the examiner's table. Secondly, every candidate is requested, "for the good of the class," carefully to indicate all the subjects on which the new examiner exhibits his learning; and so, in a brief period, is the just terror in which the examiner should be held most effectually removed: he is *gauged* and filed off.

From a knowledge of examiners, the grinder leads his pupils to a knowledge of things; not a new bottle or preparation finds its way to the examining tables that has not, almost simultaneously, its counterpart on the table of the grinder. "Gentlemen, at the hall they will show you this bottle; mark its appearance, and observe that when it is shaken the substance within gives out a metallic ringing sound; only look at this specimen well *here*, and you will be sure to know it well *there;* for the two are precisely similar."

Your leader seven years ago, sir, well exposes the botanical part of the hall examination. "The young gentlemen who, in the fields, would have been puzzled between a nettle and a dock, had the story all pat; natural order, sexual position, class, genus, species, name, habitat, nothing was wanting; but the uniformity of the extent of botanical knowledge begat suspicion, and it was by and by discovered that the specimens paid toll of branch and blossom each on its passage thither" (to the hall). At the present day the same system of fraud exists in all its fulness; still may every candidate for the hall licence, for the small sum of half-a-crown, have a packet of specimens exactly like those sent to the examination tables, each flower duly labelled and described; perhaps, indeed, the thing is done even in better style now than it was formerly, for the cunning botanist, anxious that the lovers of Linnæan science with whom he speculates, should not betray the secret by knowing too much, either avoids giving "the full complement," or else perpetrates an intentional mistake on one of the labels. Thus charged with botanical lore, the student boldly meets the enemy, daring even to walk to Blackfriars with the Chelsea *bouquet* in his buttonhole; and to sit with it, labels and all, in his breast pocket, side by side with his examiner.

Still further, the professors of cramming know their evil art so perfectly, that they are able to apprise their pupils of the very disposition of each examiner, and of the behaviour that will best suit him. "If you get Mr. A, gentlemen (whom you may at once recognize by such and such peculiarities), you may rest pretty easy in your minds; he is very kind and gentlemanly, and is always unwilling to reject any man who knows his Pharmacopœia. Look well over that book, then, and always remember that the subjects in it come alphabetically; so that in searching for anything to which he shall direct your attention, you may be able to open upon the right place with the air of a person who is familiar with the learned volume in question, and understands it from its alpha to its omega. If you get Mr. B, you will find him strictly practical, so be sure to narrate all the cases you have seen, and especially midwifery cases. If you get Mr. C, you will find him pettish, very fond of putting catch questions, as the Latin derivation of hæmoptysis (a word you will remember really derived from the Greek); he will also make a little fun of you perchance, and tell you that you know no more of your profession than a governess or a washerwoman. Well, these mere insults you must suffer resignedly, as there is no escape from them except by the way of rejection, which is not desirable; and you will then get on so as to pass with him also; only take care, by the way, not to admit to this gentleman that you studied in Scotland, if such be the case, for he has a most sneering antipathy to all medical schools and professors on the other side of the Tweed, and would like if he could to pluck you for the very admission." Thus, one after the other, does the grinder describe the whole examining board, *in truthful style.*

The sum, sir, that the pupil has to sacrifice for this grinding advantage, or rather disadvantage, is five pounds, and it is understood that for this sum the grinder *shall* get him through. Thus may the pupil be ground and rejected—ground and rejected, as many times as he pleases; he is no worse, except that he loses time: the grinder bears all the trouble. The mode in which the grinding class is conducted also is of the most artful kind. The pupil is always at the "commencement of the course," join when he may; the subjects being taken up in such a manner as to form a circle safely perambulated in no more than three months. "Keep to this circle, gentlemen," says the grinder, "and you are safe, for it girths fairly the body medico-intellectual of Apothecaries' Hall."

The rapidity with which the grinders cram their pupils is incredible. Young men who would confound a voltaic pile with the pile of a bridge, or the scales of leprosy with the scales in libra, are in the course of a few weeks, by constant daily repetitions, made to go through decompositions that would take a Berzelius months properly to understand, and to rattle off the symptoms of diseases like consummate nosographers. Still more, the system is managed so adroitly (especially by the older grinders), that there is no telling, either by cross-examination or any other means, that the answers are ground ones: the student seems to know the whole subject perfectly, and yet all he utters is a mere mechanical act of the lip, in which reason and thought play no part; and so flimsy is the knowledge, that to break the chain of repetition for two days, is to go back as many weeks.

But to cram the deceived wretch in this way is not the only part of the grinder's business; he has also to watch for the exact period for sending him to the examining board; and the proper moment for this he understands so well, that in ninety-nine cases out of the hundred the man he thus sends shall pass. It may be, however, that the pupil must go up before his hour of maturity in grinded lore shall have come, in which case he is taught an almost never-failing method, that—viz., of shirking his weak points, and of quietly parading his strong ones; for it is part of the grinder's creed "that gentlemen pretty well up on one or two subjects, may by a little dexterity avoid all appearance of ignorance, and that generally speaking it is the student who leads the examiner into different subjects, not the examiner the student." Again, if the candidate is weak on all points, he is taught to employ his time until the evil day arrives in getting up his Latin, and those subjects which are usually preliminary and most common; that is to say, he is instructed to take the edge off his examiners by a large display at first, with some plausibility afterwards; and such a man is said "to have a chance of getting through *with a squeeze;*" and often does so. Lastly, if a student goes up against the will of the grinder, *he is always rejected,* and the grinder tells him that he would rather have returned him his money than have had his class disgraced by such impatient folly; and this in fact would be better for the grinder, since he must himself bear all the load of the dishonour; for, as your leader of 1844 observes very rightly, "It is the business of these gentlemen to get the student through, rather than his own; if they fail, the blame attaches to them rather than to him, and in this light is the thing actually viewed. It is not said, that Mr. So-and-so was plucked last night, and that Messrs. So-and-so passed; but it is, one of Power's men, or one of Steggall's men was plucked last night, and seven or more of Power's or Steggall's men passed."

But, sir, there is a more grievous evil in connexion with this system than any I have yet narrated, and it is this—so certain is the grinding process in its results, and so common has it become, that good and worthy students are entrapped into the habit of adopting it. To speak plainly, they are almost driven to adopt it; for so accustomed are the examiners to receive the prepared and mechanical answers of ground men, that they can listen calmly to no other. They are like some epicures, who from long custom get to loathe all food that does not come to them dressed after a certain system. "Sir," says the grinder to his really intelligent pupil, "you know your profession excellently well, but you

do not know how to answer questions in hall fashion. I must beg you, therefore, in your descriptions to avoid giving an account of things in the same unclassified way that you have seen them, and to follow me in what I say." "But, sir," remarks the student, "what you say is sometimes incorrect; I know that your answers are not always in accordance with facts, or up to the knowledge of the present day." "Never mind," replies the grinder, doggedly, "mine is the *hall way* at all events; and if you are anxious to get the hall diploma, it will be wise for you just to cast off your own views, *pro tem*, and to content yourself with mine." Such is the grinding method. How true is the writer before alluded to, when he exclaims, "Oh! it is a vicious and unworthy system: it is a cheat and a lie."

And, sir, when I affirm that nine out of ten of all the students who go up to the hall for examination, pass through this debasing ordeal, how, I ask, can the examiners of the hall affirm with any approach to truth, that candidates for their diploma are worse informed in matters of preliminary than of medical education? A student appears before them, with his head charged like a bomb; the whole medical information of the eleven examiners, as far as it can be known, thrust into that one unfortunate cranium, with *et ceteras*. The examiner commences with Latin, but the mind of the candidate is too deeply occupied with nosology, toxicology, and chemical decompositions, to remember much of the language of Cæsar. He may have known it pretty well once, but now *hic et hæc* are lost in, or confounded with, *ic* and *ous*, *ite* and *ate*; and so after considerable bungling, the examiner, greatly disgusted, has to take him on to other subjects; and now the time of action comes, and the bomb bursting scatters around such stores of condensed learning, that the examiner stares, unable to comprehend how so Latinless a mouth could pour forth such torrents of medical information. The conjurer, in fact, in extracting bushels of feathers from an empty hat, does a small wonder in comparison; yet such a student when he returns to obtain his licence, shall receive from the president "the compliments of the court," coupled, however, with the gentle hint, "that it would be well for him to acquire a little more Latin, if it were only for the purpose of being able to teach the rudiments of that fine language to the young olive branches that at some future period may bedeck his table." Alas, poor president, and innocent court! little do they think that the knowledge they would compliment has already no existence; that the medical contents of that surcharged head were scattered and delivered, to all the winds of heaven, and that the little Latin which they criticise is almost the only thing which the now emptied candidate retains; except, perchance, a recollection of their compliments, and these only to laugh at, and relate for sport on jovial occasions.

Or to take another view: a candidate for the diploma, who has been too proud to debase himself with "the grind," and who trusts to good practical and general information, goes to the examination table. Questions are there put to him on subjects which he knows intimately; but his answers he finds do not suit. They are not *ground* answers, and so he gets uneasy and uncollected, and after being tantalized for a long time, is dismissed—not rejected perhaps, but feeling degraded to the last degree, his whole soul smarting with a sense of insult, and his tongue declaring that if he has deserved the cruel treatment he has received he has not deserved the licence; or that if he deserved the licence, he did did not deserve the degradation to which he has been subjected. These, sir, are no overdrawn pictures; the statements I make are based on painful facts, and knowing them to be true, again I ask how, under such a state of things, is it possible for the hall examiners to pronounce on preliminary and medical education? They hold councils it is true, and pass judgment on candidates for their licence; but really and truly, as matters are carried on, they have no more knowledge of the actual available medical acquirements of those whom they examine, than they have of the theological acquirements of the Grand Lama of Thibet.

The thing is plain. Before the value of preliminary education can be brought out, *this grinding system must be abolished;* the latter nullifies the former. What matter is it to the public if a young man, who on leaving his school or his home, can speak Latin like Cicero, Greek like Demosthenes, or work out mathematics like Euclid? What is all this to the health-seeking public, if the same young man is afterwards licensed to treat disease with no further knowledge of the principles on which disease should be treated than he has acquired in three months with a grinding master? Is walking Southampton-street or Exeter Hall, what the public understand by walking the hospitals? Will the compact knowledge of all the professors of grinding in London, transfused with something more than hydraulic pressure into this classical young man's brain, help him afterwards in restoring by skilful services glad hearts and laughing eyes to children threatened with orphanage, or in returning the dying babe, full of life, to its mother's heaving bosom? Alas! no. The practitioner thus qualified, in nineteen cases out of twenty fails in all his duties to society, mostly continues a very quack, a cheat both to himself and to the world, and though by habit he may get into *a way* of treating disease, yet does he never advance; his so-called experience but confirming him in the errors with which he had started in his career.

But it may be asked, how are these evils to be remedied? I answer, by a change in the whole system of licensing men as medical practitioners. It has been said to me that grinders will ever exist, because, forsooth, examiners will always have peculiarities; and indeed it must be admitted that men will ever ride hobbies, but surely it would not be difficult, by increasing the number of examiners and changing the men, so to increase and change the hobbies as to baffle even a grinder. The root of all the mischief, in truth, rests in the fact that these examiners are too few in number, and that they hold their offices too long. I write with all deference to these gentlemen, and would not willingly offend them; but truth compels me to ask, is it not a grievous thing that by far the most numerous portion of the public should have to depend for persons into whose hands to commit their dearest lives, on the judgment of eleven men—"gauged" men withal—whose acquirements, as far as examinations are concerned, may be learned and successfully taught in twelve months, by any clever fellow who chooses to turn his talents to so unworthy a purpose? Is this reasonable, just—a thing worthy of a liberal and most useful profession?

We medical men chide the public for patronizing quackeries, from homœopathy downwards, and in this we act properly; but well would it be for us at the same time, one and all, to combine for the purpose of setting a proper guard over the portals which admit strangers into the temple of medicine—a guard past which no grinder, by any subtlety, could conduct men deficient in a knowledge of the first principles of their profession.

I have thus, sir, expressed myself most freely on my subject; and I have done so, not from any animosity to the Apothecaries' Company, but for the purpose of showing how great a change must take place in the examining system generally, before any good from preliminary instruction can follow. So long as examinations consist of mere question and answer, and are left to ten or twelve known individuals, examiners, however eminent, will still be "gauged" by the grinder, and ignorant men pass by the examination table into places where good men only ought to stand.

But let these examinations, sir, be conducted by many able men, chosen in turn, and frequently, from all parts of the profession; let them be examinations according to the highest standard, open to all, irrespective of the where, the when, or the how the candidate has studied; let them be clinical and practical examinations, conducted at the bedside, in the dissecting-room, in the laboratory; and, above all, let weeks or months take the place of the hours now occupied in examinations; and then would the grinding system die out of itself, and the public receive in all cases the substance for what is now too often the shadow of the competent practitioner of medical science.

There are, sir, many more errors in the present system of examination which might be pointed out with advantage; but already have I trespassed far too much upon your columns, for which trespass I have only one apology—the great importance of the subject.—I have the honour, sir, to remain your most obedient servant, OBSERVATOR.

The state of affairs here depicted, we would fain believe, is not the universal one: on the contrary, we believe that many are engaged in the preparation of students for examination who hold the "mere grinder" in as much contempt as the writer of the above. To reject the method of instruction by examination because it is exclusively adopted by any class of teachers, and conducted in a dishonest way, would be just as wise as to reject the method by lecture because the same persons "grind" in that way.

It is obvious that the period has arrived for making this most valuable resource available for surgical education in a legitimate and unexceptionable manner, and that instead of branding a respectable instructor with the opprobrious nickname of "grinder," he should be distinguished by a title indicating his real duty. At the same time we are not so sanguine as to think that the race of true "grinders" will become extinct; nay, we cannot say that it would be safe or convenient to dispense with their services; for as long as dunces, blockheads, and idlers are admitted into our profession, and cherished by the public, so long must we tolerate the only operator capable of shaping them. Moreover, we look upon such a refuge for the destitute as a great relief to the more legitimate teacher, who would otherwise suffer interruption from the continued presence of pupils incapable of learning in the usual way. While considering this subject it may be well to allude to an application of the grinding system which it is said begins to prevail: it is, we believe, called "grinding over the subject," and consists in a kind of lecture or demonstration in anatomy restricted to the known "points" of the examiners for the time being. This, although undoubtedly an improvement on the mere question-and-answer plan, leads to a substitution of these picked demonstrations for the regular courses of lectures on Anatomy and Physiology required by the College regulations, and to the granting of certificates for a description of instruction never given. Indeed it seems as if the teaching of anatomy and physiology, which formerly constituted the principal and most attractive department of the medical and surgical schools, is about to be discontinued altogether, the Colleges not requiring lecturers in this branch to produce proofs of qualification for the duty, or of any means of instruction beyond the recent dissection.

THE WAR AGAINST QUACKERY.

Whether for good or evil the English medical press has declared open war against the quacks within the pale, and against the homœopaths, and mesmerists especially. It would ill become us to fail to "bear a hand" in the common effort to eject these minions of the credulous from amongst us, and therefore do we from time to time give circulation to the fulminations of our contemporaries against them; although our profession does not perhaps suffer so much in this way here as in England. We are the more inclined to aid in this praiseworthy movement, because we perceive that it is not to be confined to the disciples of Mesmer and Hahnemann, but is to be extended to still more guilty delinquents. For some years the medical profession in Ireland has been insulted and scandalized by a most shameless display of barefaced disregard of all obligations in the shape of advertisements, and any proceeding which promises to abate the nuisance shall have our hearty concurrence. In England the plan seems to be more one directed to the punishment of the accomplice than the actual criminal, and so it should be here. The man who glories in infamy and courts contempt in daily appeals to the base and sordid feelings of the dregs of society, is invulnerable; but not so his accomplices: let those who coöperate with such by consultation or otherwise be treated as accessories, which they really are, and the effect will soon become apparent. The College of Physicians of Edinburgh has done its duty, and other colleges have followed its example, but we cannot say that the College of Physicians of Dublin has displayed any peculiar sensitiveness touching the contaminations of quackery. A guinea we hear is not considered of less value because it comes in consultation with a quack, and a colleague is not the less respected because he is the colleague of a medical reprobate:—

The medical profession is now thoroughly roused from its lethargy, and there is very little risk of its returning to carelessness or torpor, on the subject of quackery. But there is some danger that the fervid and honest spirit now universally evinced may be misdirected. Our earnest desire is to see the profession prosper and retain in public estimation the place bequeathed by the great men who have gone before us. This we doubt not will be achieved in spite of all the pestilent heresies Germany and France can vomit from their perverted bosoms. To such the only answer is, Look to statements and arguments, and if you find aught to gainsay or contradict, let us hear it. If not, personal objections conceal a spirit of as much weakness and falsehood as personal attacks. We ask such men to join in chasing dishonesty and imposture from the ranks, and they reply by cavilling and seeking to rouse prejudice against the hand which helps them. The truth is, they prefer the darkness to the light, because their own deeds are evil. We warn the profession against a trick of which many signs may be observed. The favourers of quackery, conscious that the indignation they have roused is too general and too deep for resistance, would make a sacrifice of homœopathy, as mariners in distress throw a tub to the whale in its fury. They would turn the whole of our anger against this particular fraud, and purchase an unlimited indulgence in other directions. This device, did it succeed, would do great honour to the followers of Hahnemann; but let the allies of quackery know that the feelings of the medical profession towards homœopathy are not free from contempt, while mesmerism and other forms of quackery in doctrine and conduct are viewed with unmixed and unrelenting censure, because all of these are accompanied with incidents of the most impure and demoralizing tendency. Could they take root among us, and were they established as ordinary resources in physic, they would drive doctors out of every honest home as dangerous corrupters; and we are well assured that the fumbling of mesmerists and unscientific proceedings of other species of quacks, have already led to seduction and profligacy on a more extended scale than would be readily believed. The medical profession must not be so seriously disturbed merely for the purpose of getting rid of such puerile nonsense as globulism alone, which would have died of ridicule and contempt long ago, had it not been fostered by the hangers-on of royalty and fashion. We must be careful to take with us the good wishes and aid of the public, which would be withheld from any partial repression having an air of persecution. Let the knaves perish together, and let us abide by truth in all things. If we do not adopt these large views, we shall be defeated, even by the weak and shallow beings who, in medicine as in theology, make constant but false appeals to liberty of opinion in defence of their invariable illiberality. Their impudent and braggart philosophy pollutes the sacred name of science everywhere; it exhibits the utmost keenness in spying out the most shadowy distinctions, the greatest briskness in starting objections, and lubricity in eluding refutation; it is the stiffest stickler for all antiquated notions or new fancies which can be strained to its own ends, and its dexterity in plucking itself from the arena of debate under a *tu quoque* reproach, must never be lost sight of. Again and again we conjure our colleagues not to permit one offender to pay the penalty of the crimes of others, nor to let slip the present opportunity of thoroughly purging the profession of knaves and impostors of every class.—*Lancet.*

MARKING DESERTERS BY THE MEDICAL OFFICERS OF THE ARMY.

This question has, we have much pleasure in intimating to our readers, been at last clearly set at rest, and any doubt as to the wording or interpretation of the *late order* dispelled by the Secretary at War himself. In order that there may be no misunderstanding whatever, a circular letter has been forwarded from the War Office to the governors of the military prisons, directing that the "said marking is to be performed by the infirmary warden, or

some other subordinate officer of the establishment, in the presence of the medical officer, in as careful and efficient a manner as possible. Whilst the matter was *in doubt*, we thought it right to offer our strictures upon *the order*, but were ourselves satisfied that it never could be the intention of the authorities to offer insult to a body of men who, in the midst of deadly pestilence, or savage war, have ever been foremost in the relief of suffering humanity, and in the discharge of every duty devolving on them.

OPERATION OF THE DISPENSARY ACT.

The combination of electoral divisions in two separate unions to form Dispensary Districts, continues to be a subject of discussion. We make the following short extract respecting it from a provincial journal *(The Wexford Independent)*, to which our profession is often indebted for useful suggestions and information :—

In the present act it is provided that each dispensary district shall be made up of a certain number of *un*divided electoral divisions; but the act does not show how adjoining unions are to coöperate in uniting electoral divisions on the boundaries of two unions; or, in other words, there is no provision by which electoral divisions on the boundary of one union, however conveniently placed as regards the formation of a new dispensary district, are to be united with corresponding divisions in the other union. However, on this subject, we would recommend to the guardians so situated to take the matter quietly into consideration; and without any difficulty they can mutually apportion the districts so that the spirit of the act may be complied with, and the *lapsus* of which our legislators have been guilty can be filled by the wisdom of the intelligent gentlemen composing our boards of guardians. The greatest difficulty which presents itself to us in the application of this measure is, the classification of relief recipients. What is to be the standard whereby an applicant is to be tested? In regulating this point some difficulty must arise, as a clear course must be steered, lest by making the relief too general, the spirit of independence which the public works tended so much to lower among a certain class of our small farmers, may, by classing them amongst those who are supposed to be unable to purchase medicine or fee a doctor, be still more degraded; and in addition to this an injury might be inflicted on the local medical practitioner, whose interests are not to be overlooked, and who, it is to be remembered, accepts his appointment under the impression that he is to be permitted full liberty to practise his profession in his capacity of a private practitioner, as well as an attendant on the poor; and that his legitimate right to receive remuneration for the supply of his medicines and his medical advice is not to be encroached on.

The following has reference to the same subject :—

TO THE EDITOR OF THE MEDICAL PRESS.

Dear Sir,—Enclosed I send a copy of a letter which I sent to the Ballinasloe Board of Guardians. By inserting it in the Press, you will much oblige.

Yours truly, Joseph Pratt.

October 18, 1851.

My Lords and Gentlemen,—Preparative to your nominating the dispensary districts under the new dispensary act, I would beg leave to suggest that my dispensary district be comprised of the electoral divisions of Killuan, Kilconnell, Ballymacvard, and Killalarton in the Ballinasloe union, also the electoral divisions of Grange and Killimerdaly in the Loughrea union, which are at present in my district. These electorates are adjoining each other, and all in my immediate vicinity, and I am of opinion it would be expedient for the Ballinasloe and Loughrea guardians to coöperate in forming such a district; by so doing they will save both unions a considerable expense, as one dispensary will be quite adequate for the above electorates. I may mention that my residence at present is nearly the centre of these divisions.—I remain your obedient servant, Joseph Pratt,

Medical Superintendent of the Killane Dispensary, Kilconnell.

To the Chairman and Board of Guardians, Ballinasloe.

THE MEDICAL COMMISSIONER.

Up to the time of our going to press no appointment has been made. It is, however, generally believed that a gentleman, on whose integrity our profession can rely, will be the person chosen.

M. W. HANLON, M.B.

PROFESSOR PORTER'S SURGICAL WORKS.

OBSERVATIONS ON THE SURGICAL PATHOLOGY OF THE LARYNX AND TRACHEA,

Chiefly with a view to Illustrate the Affections of those Organs which may require the operation of Bronchotomy.

OBSERVATIONS ON THE SURGICAL PATHOLOGY AND TREATMENT OF ANEURISM.

By William Henry Porter, M.D,

Surgeon to the Meath Hospital and County Dublin Infirmary, Consulting-Surgeon to the City of Dublin Hospital, and Professor of the Theory and Practice of Surgery in the Royal College of Surgeons in Ireland, &c. &c.

Dublin: Fannin and Co., Grafton-street.

Mr. Porter is preparing for publication his Lectures on Venereal Diseases, with additional Notes and Illustrations.

THE ROYAL MEDICAL HALL,

64, DAME-STREET, DUBLIN.

☞ *Change of Proprietorship.*

BEWLEY, OWEN, and CO., APOTHECARIES,

(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS,

will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, and CO.'S ESTABLISHMENT

embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick-room and nursery.

*** GENUINE COD-LIVER OIL,

of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

SCHOOL OF SURGERY.

THE Winter Session, 1851–52, will commence on Monday, October 27.

Anatomy and Physiology—Dr. Jacob.
Descriptive Anatomy—Dr. Hart and Dr. Macdonnell.
Surgery—Mr. Porter and Mr. Hargrave.
Practice of Medicine—Dr. Benson.
Chemistry—Dr. Barker.
Midwifery—Dr. Beatty.
Comparative Anatomy—Dr. Jacob.
Dissections by the Professors of Anatomy and the Demonstrators—Dr. Leeson, Mr. Labatt, Mr. T. D. Hargrave, Mr. Malcolmson, and Mr. Morgan.

THE SUMMER SESSION WILL COMMENCE THE 3RD OF MAY.

Materia Medica—Mr. Williams.
Botany—Dr. A. Mitchell.
Medical Jurisprudence—Dr. Geoghegan.
Practical Chemistry—Dr. Barker.

The Fee for each of the above Courses is Two Guineas.

For further information apply to any of the Professors, or to the Registrar. By order,

W. BOYLAN, Registrar.

CITY OF DUBLIN HOSPITAL.

THE Winter Course of Practical, Medical, and Surgical Instruction will commence on the 27th of October.

The Clinical Lectures will be delivered by Dr. Jacob, Dr. Benson, Dr. Beatty, Mr. Hargrave, Mr. Williams, Dr. Geoghegan, and Mr. Tufnell.

Dr. Jacob will deliver a full Course of Lectures on Diseases of the Eye; Dr. Beatty, select Lectures on Diseases peculiar to Women and Children; and Mr. Tufnell on Military Surgery.

Sir Henry Marsh, Sir Philip Crampton, Professor Apjohn, Professor Porter, and Mr. Cusack, give their assistance in cases requiring consultation.

Certificates of attendance are received as qualification by all the Colleges, Halls, and Boards.

DISEASES OF THE EYE.

DR. JACOB will deliver a full Course of Lectures on the Anatomy, Physiology, and Optical Mechanism of the Eye, during the ensuing Session, in the College of Surgeons, and also a separate Course on its Pathology and Diseases, with the Operations required in their Treatment, in the City of Dublin Hospital.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT
AT
G. O. AND CO.'S MEDICAL ESTABLISHMENT,

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention;* to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. AND CO. CONTINUE TO BE SUPPLIED WITH THE FOREIGN MINERAL WATERS FRESH FROM THEIR VARIOUS SPRINGS.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

ROYAL COLLEGE OF SURGEONS.

SCHOOL OF SURGERY.

THE Session 1851–2 will not commence until the 27th of October. Gentlemen, however, residing in Dublin can commence their Dissections immediately on entering their names for the ensuing Winter Course of Practical Anatomy.

THE
RICHMOND SURGICAL, WHITWORTH MEDICAL,
AND
HARDWICKE FEVER HOSPITALS,
North Brunswick-street.

THE course of attendance and Clinical Lectures at the above mentioned hospitals will commence on Saturday, the 1st of November, 1851, at ten o'clock, a.m., when Dr. Corrigan will deliver the Introductory Lecture. The Course will be continued during the Winter and Summer Sessions.

These hospitals contain 300 beds, and have attached to them the Talbot General Dispensary, the Lunatic Asylum at Island Bridge, and the Truss Establishment for the Relief of the Ruptured Poor of Ireland; also a well-selected Medical and Surgical Library.

There is also an extensive Museum, containing nearly four thousand Morbid Preparations, Casts, and Drawings, available for clinical instruction, and accessible to the hospital class at all times.

The Surgeons visit daily at half-past eight o'clock, and the Physicians daily at ten o'clock a.m.

Two Surgical and two Medical Clinical Lectures will be delivered each week.

The resident pupils and clinical clerks of the Richmond, Whitworth, and Hardwicke Hospitals are selected from the class according to merit.

Two prizes will be given at the end of the Winter Session—one in Clinical Surgery, and one in Clinical Medicine.

The instruction in Clinical Medicine is given by—
Dr. Corrigan, M.R.I.A., Physician in Ordinary to the Queen in Ireland, Lecturer on the Practice of Medicine in the Carmichael School of Medicine, &c.;
Dr. Banks, M.R.I.A., Honorary Fellow of the King and Queen's College of Physicians in Ireland, King's Professor of the Practice of Medicine;
Dr. McDowel, F.R.C.S.I., Lecturer on Anatomy and Physiology in the Carmichael School of Medicine, &c.;
Dr. Gordon, F.R.C.S.I., M.R.I.A., Physician to the Government Lunatic Asylum at Island Bridge.

The instruction in Clinical Surgery is given by—
Dr. Hutton, M.R.I.A., Vice-President of the Royal College of Surgeons in Ireland, Surgeon to Simpson's Hospital, &c.;
Dr. Adams, F.R.C.S.I., M.R.I.A., &c.;
Dr. MacDonnell, F.R.C.S.I., M.R.I.A., Professor of Practical and Descriptive Anatomy in the Royal College of Surgeons in Ireland, &c.;
Mr. Hamilton, F.R.C.S I., M.R I.A., Examiner in Surgery to the Queen's University, Lecturer on Surgery in the Carmichael School of Medicine, &c.;
Dr. R. W. Smith, F.R.C.S.I., M.R.I.A., Professor of Surgery in the University of Dublin.

In the immediate vicinity of these Hospitals is the Carmichael, late the Richmond Hospital, School of Medicine, where regular courses of lectures are delivered on the several subjects of medical science.

Attendance for nine months on the practice of a General Hospital, with attendance on the Clinical Lectures on Medicine and Surgery therein delivered, is, by a recent regulation of the Board of Trinity College, required from candidates for the degree of M.B.

The London College of Surgeons require a list of the pupils entering for the Winter Session, to be transmitted to their Secretary, on or before the 25th of November next.

Terms of Attendance.

For the Winter Session of Six Months, ... Eight Guineas.
For the Summer Session of Three Months, Three Guineas.

For further particulars apply to the Secretary, Dr. Hutton, 29, Gardiner's-place, or at the hospitals.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin.
London: John Churchill, 46, Princes-street, Soho.

THE Royal College of Surgeons in Ireland grants two different diplomas—one conferring the rank of Fellow, and the other that of Licentiate. The Fellow is a member of the corporation, and entitled to vote at all elections for president, vice-president, and councillors, and also to be elected president, vice-president, or member of council. The Letters Testimonial granted to the Licentiate enables him "to exercise and enjoy all rights of practice in the art or science of surgery, or otherwise, which are commonly enjoyed by the Fellows, and to have free access to the library and museum of the College, and makes him eligible to the rank of Fellow, subject to specified regulations." Both Fellows and Licentiates are obliged to make and subscribe a formal declaration legally binding them "to observe and be obedient to the statutes, bye-laws, and ordinances of the College, and to the utmost of their power to promote its honour, reputation, and dignity." Fellows, in addition, declare that they "do not practise the business or profession of an apothecary or druggist, or indirectly sell drugs or medicines, and that they will not, while Fellows, practise such business or profession." The charter also provides, "that if it shall at any time hereafter appear that any Licentiate or Fellow shall have obtained his diploma by any *fraud, false statement, or imposition*, or that *either before or after* obtaining such diploma, he has wilfully violated any bye-law, rule, or regulation of the College, the Council may censure him, or if expedient, recal and make void his diploma, and expel him.

A student who proposes to become a Fellow or Licentiate of the College must first become a registered pupil, for which he pays a fee of five guineas; but he is permitted to postpone such entry as registered pupil and such payment until the period of his final examination.

The fees for the diplomas are as follows:—For Fellowship, twenty-five guineas, in addition to the registration fee of five guineas; thirty guineas in all. But if the candidate has already passed as a Licentiate, and paid the registration fee of five guineas, and twenty guineas, the fee for Letters Testimonial—twenty-five in all; he is required to pay a Fellowship fee of ten guineas only, should he propose to become a Fellow. If a person becomes a fellow at once, he pays thirty guineas; but if he commences as Licentiate, and afterwards passes as Fellow, he pays thirty-five guineas in all—viz., five guineas registration fee, twenty guineas for Letters Testimonial, and ten guineas for Fellowship. For the licence or Letters Testimonial alone, the candidate pays five guineas registration fee, and twenty guineas for the final examination—twenty-five in all. The student who becomes a registered pupil as soon as he commences his studies in Dublin, is thereby matriculated in the College, and entitled to its protection, aid, and guidance. Fellows of the College who settle to practise in Dublin, are required to pay ten guineas in addition to their other fees.

Fellowship.—The candidate for the Fellowship must be twenty-five years of age, and if not a graduate in arts

of some university, must be prepared to answer a classical examination, which is generally confined to the principal books read for entrance into Dublin University. He must have been six years engaged in professional study, three of which must have been in Dublin; and he must also have been a house-surgeon or dresser in an hospital. He is required to attend lectures on anatomy and physiology, and on surgery with dissections during three seasons, chemistry during two, and practice of medicine, materia medica, midwifery, medical jurisprudence, comparative anatomy, natural philosophy, and botany, for one course each. His hospital attendance must be three years at least. Bachelors of Arts, after five years' study, are admitted to examination on compliance with the above regulations; and Licentiates of the College of ten years' standing are also admitted, although they may not have been educated in strict conformity with them.

Letters Testimonial.—The candidate for Letters Testimonial is required, as has been already stated, to become a registered pupil, and to pass a classical examination. He is also required to prove that he has studied for *three* years in the metropolitan schools (nine months in each year), and for a fourth year either there or anywhere else, where he might have obtained professional information. His hospital attendance is by the bye-law declared to be *three years* "where clinical instruction is given," and all the Dublin hospitals are recognized. Credit is given for attendance on provincial hospitals, but it is expected that while the pupil is in attendance on lectures in Dublin, he shall, at the same time, attend an hospital there. Candidates for Letters Testimonial are also required to prove that they have attended three courses of lectures on anatomy and physiology, surgery, and practical anatomy (being demonstrations with dissections), two courses on chemistry, and one course on the practice of medicine, materia medica, midwifery, and medical jurisprudence.

Candidates both for the Fellowship and Letters Testimonial are examined on the *practice of medicine and pharmacy* as well as on surgery. The diploma is a full qualification as General Practitioner, entitling the holder of it to be appointed to county infirmaries, fever hospitals, dispensaries, poorhouses, and all other medical charities. They can also practise medicine as fully and freely as Doctors of Medicine, or Fellows or Licentiates of Colleges of Physicians; and *Licentiates* of the College can dispense medicines to their own patients; but they cannot keep open shops, or retail drugs, or compound the prescriptions of other practitioners without the licence of the Apothecaries' Company. Both Fellows and Licentiates are authorized by law, and permitted by the charter, to compound and dispense medicines for their patients in the hospitals, dispensaries, and poorhouses to which they are attached. None but Fellows and Licentiates of this College are eligible to be appointed Surgeons of County Infirmaries in Ireland.

The College of Surgeons of Ireland is empowered by charter to grant a diploma in midwifery to its own Fellows and Licentiates only; *and does not recognize any of them as midwifery practitioners, or mark them as such in the printed lists of the College, unless they have had that diploma granted to them.*

Certificates granted by professors in universities which do not receive the certificates granted by the professors in the College of Surgeons, are not recognized as qualification from candidates for either of the diplomas.

Certificates of attendance on *lectures* delivered in Ireland are not received as qualification for either of the diplomas of the College, unless the professors or lecturers who have granted them have been duly recognized as *professors or lecturers* in consequence of proof given that they "have acquired, either by education or practice, such ample information on professional subjects generally as is required from candidates for the fellowship," and that they "have enjoyed such opportunities of acquiring information on the particular subjects upon which they propose to lecture as the Council may consider necessary to qualify them to perform that duty."

Returns of the names of those who have entered to attend lectures, are required to be forwarded to the College by professors and lecturers on the 25th of November, and at such other periods during the session as the Council may think fit; which returns must certify that the students named therein are then attending regularly; and no certificate is received from any candidate for either of the diplomas unless his name appears in the returns corresponding to the date of such certificate. Professors or lecturers neglecting or refusing to make such returns, or who grant certificates to any student whose name has not been inserted in such returns, are not recognized.

Students are admitted to the classical examination required by the bye-laws without being required to become registered pupils, or to pay the registration fee of five guineas; it being considered desirable that pupils on their first arrival in Dublin, and as soon as they can conveniently do so after leaving school, should pass this preliminary trial, and not postpone it until the period of their final examination for Letters Testimonial. They have only to present themselves at the College, and to pay a fee of five shillings to enable them to offer themselves; and if approved, the certificate required by the bye-laws to be produced by candidates for Letters Testimonial is granted to them. On payment of five guineas at any subsequent period, they are enrolled as registered pupils, and become entitled to study in the museum and library, and to attend the lectures on comparative anatomy. They are examined in the Gospel of St. John in the Greek Testament, and in the first five books of the Æneid of Virgil.

The following ordinance of Council was made April 9th, 1851:—

"To enable surgical students to devote more time to hospital attendance and dissection during the winter session, the lectures on materia medica, medical jurisprudence, practical chemistry, and botany, shall be delivered during the summer session, in the School of the College, and in the schools recognized by the College. To secure due attendance on hospital practice by the student for the full term required by the bye-laws, certificates of such attendance during the summer session shall be granted separately from those granted for the winter session. Certificates granted subsequent to the 30th of April, 1851, shall not be received as qualification for Letters Testimonial unless issued in conformity with these regulations."

This being a very important alteration, requires some explanation to make the student aware of its object and operation. Hitherto summer courses of lectures on a few subjects have been delivered to accommodate students required to remain in Dublin during the months of May, June, and July, to complete the hospital attendance of three years. These courses having, however, been found insufficient to secure the necessary means of instruction during this period, and the attendance of students on hospital practice at the same time having become irregular and imperfect, a more complete and efficient arrangement

was called for, and has been adopted both in Dublin and London. Surgical education is, in fact, to be regularly conducted in future from the beginning of April to the end of July, so as to enable the student to divide the required attendances more equally over his four years of study; and certificates of attendance on summer courses delivered in winter, or on winter courses delivered in summer, are not recognized. The lectures on materia medica and medical jurisprudence, heretofore delivered in winter, are henceforward, therefore, to be delivered in summer; and no certificate of attendance on winter courses on these subjects will be received. Lecturers on these subjects who disobey the above ordinance, and deliver their lectures in winter to accommodate persons obliged to rest satisfied with an irregular and imperfect surgical education, do so under a mistaken notion that their certificates may pass in London; but as the London College directs that candidates for their diploma, who shall have studied in Ireland, must produce certificates of lectures as "delivered in Ireland;" and as the lectures in question are delivered in the College of Surgeons in summer, in obedience to the College ordinance, this view is evidently erroneous.

On the 4th of December, 1850, the Council of the College adopted the following resolution with reference to the bye-law which enjoins that "certificates shall not be received from teachers or professors in colleges or other institutions which refuse to receive the certificates of professors in the College of Surgeons":—

"The Council being anxious to encourage liberal education among candidates for Fellowships and Letters Testimonial, in future all *graduates in arts* of the University of Dublin, being registered pupils of the College of Surgeons, shall be admitted to the examinations for Fellowship and Letters Testimonial, provided they produce the certificates of surgical education required by the bye-laws, and of such course of education the several certificates of the School of Physic, *now* required by the 'regulations of the University to be produced by candidates for the degree of Bachelor of Medicine, shall be received as part.'"

The Board of Trinity College not having reciprocated to this resolution in accordance with the terms of the bye-law, notwithstanding its adoption at their suggestion, Bachelors of Arts, being Licentiates of the College of Surgeons, may be disabled from availing themselves of the advantages it offers.

The following are the educational bye-laws in detail:—

1. *Registration of Pupils.*

Every person requiring to be registered as a pupil on the College books, shall, if the Council think fit, be so registered, if he shall have laid before the Council a receipt, showing that he has lodged, to the credit of the College, in the Bank of Ireland, a registry fee of *five guineas*. Registered pupils are admitted to the classical examination at the time of registry, or at any time previous to the final examination for Letters Testimonial. Students, not being registered pupils, are admitted to the same examination on payment of five shillings.

2. *Qualifications of Candidates for Letters Testimonial.*

Every registered pupil shall be admitted to an examination for Letters Testimonial, if he shall have laid before the Council the following documents:—*a.* A receipt showing that he has lodged a sum of *twenty guineas* in the Bank of Ireland, to the credit of the President, and for the use of the College. *b.* A certificate from the examiners of the College that he has passed an examination as to his acquaintance with the Greek and Latin languages. *c.* Certificates showing that he has been engaged in the study of his profession for not less than *four years; three* of which shall have been passed in attendance on lectures or hospitals in Dublin, London, Edinburgh, or Glasgow. *d.* Certificates of attendance on an hospital recognized by the Council, where clinical instruction is given, during three years. [An attendance of nine months in each year is accepted.] *e.* Certificates of attendance on *three* courses of lectures on anatomy and physiology, *three* courses of lectures on the theory and practice of surgery, and of the performance of *three* courses of dissections, accompanied by demonstrations; also certificates of attendance on *two* courses of lectures on chemistry; or one course of lectures on general, and one on practical chemistry; *one* course of lectures on materia medica; *one* course of lectures on the practice of medicine; *one* course of lectures on midwifery; and *one* course of lectures on medical jurisprudence.

3. *Examination of Candidates for Letters Testimonial.*

The examinations of candidates for Letters Testimonial shall be held from time to time, as the Council may direct. Five examiners at least shall be present at each examination. Each candidate shall be examined upon anatomy, physiology, the theory and practice of medicine and surgery, materia medica, and the form of prescription; and shall perform such surgical operations or dissections, or explain such anatomical and pathological preparations as the examiners may require. Candidates whose answering shall be found insufficient will not be allowed to present themselves a second time until after the expiration of six months from their first examination.

4. *Qualifications of Candidates for the Fellowship.*

Every registered pupil or Licentiate shall be admitted to examination for the Fellowship if he shall have laid before the Council the following documents:—*a.* A receipt showing that he has lodged in the Bank of Ireland, for the use of the College, the sum of *ten guineas*, in case he is a Licentiate, or of *twenty-five guineas*, in case he is a registered pupil; provided, in either case, he intends to reside beyond ten miles from Dublin. [Should the candidate intend to reside in Dublin, or within ten miles thereof, he shall lodge, if he is a Licentiate, twenty guineas; or if he is a registered pupil, thirty-five guineas. Fellows entering on the country list, who may subsequently settle as practitioners in Dublin, or within ten miles thereof, shall pay ten guineas to the College.] *b.* A certificate that he is twenty-five years of age. *c.* A certificate that he is a Bachelor of Arts of some university, or that he has been examined in such manner as the Council may, from time to time, direct, with a view to ascertain that he has obtained a liberal preliminary education. *d.* A certificate signed by two or more Fellows of the College, of good general conduct during his professional education. *e.* Certificates that he has been engaged in the acquisition of professional knowledge for a period of not less than *six* years; during three of which he must have studied in one or more of the schools and hospitals of Dublin recognized by the Council. He may have studied for the other three years in any school or schools of the united kingdom, which shall be approved by the Council, or in any foreign school of repute. It is also required that the candidate shall have had opportunities of practical instruction, as house-surgeon or dresser, in a recognized hospital. *f.* Certificates of attendance on the several courses of lectures required to be attended by candidates for Letters Testimonial, together withone course of lectures on comparative anatomy, one course of lectures on botany, and one on natural philosophy. *g.* A thesis on some medical subject; or clinical reports, with observations of six or more medical or surgical cases taken by himself. *h.* Candidates of the required age, who shall have taken the degree of Bachelor of Arts in a British or Irish university, and have complied with the foregoing regulations in other respects, will be admitted to examination at the end of five years of professional study; of which three years must have been passed in one or more of the recognized schools or hospitals of Dublin. *i.* Licentiates of the College, who may not be able to show that they have fol-

lowed the course of study specified in the preceding regulations, may, at the expiration of ten years from the date of their diploma, be admitted to the examination required for the Fellowship, provided they produce such evidence as shall be satisfactory to the Council that they have conducted themselves honourably in the practice of their profession.

5. *Qualifications of Candidates for the Diploma in Midwifery.*

Any Fellow or Licentiate of the College shall be admitted to an examination for the diploma in midwifery, upon laying before the Council the following documents:—*a*. A certificate showing that he has attended one course of lectures on midwifery and diseases of women and children, delivered by a professor or lecturer in some school of medicine or surgery recognized by the Council. *b*. A certificate showing that he has attended the practice of a lying-in hospital, recognized by the Council, for a period of six months; or the practice of a dispensary for lying-in women and children, recognized by the Council, and devoted to this branch of surgery alone. *c*. A certificate showing that he has conducted thirty labour cases at least. Candidates for the midwifery diploma shall be publicly examined on the organization of the female; the growth and peculiarities of the fœtus; the practice of midwifery; and the diseases of women and children; and if approved of, shall receive a licence or diploma certifying the same.

6. *Regulation of Schools.*

Certificates shall not be received for attendance on lectures delivered in Ireland, unless from teachers in schools permitting the visitation of the Council, and receiving their sanction. Neither shall certificates be received from teachers or professors in colleges, or other institutions for medical or surgical education, in Great Britain or Ireland, which colleges or institutions refuse to receive, as qualifications for a degree or licence, the certificates issued by professors in the College of Surgeons; nor shall certificates be received from teachers who deliver lectures upon more than one distinct subject, as hitherto allotted to professors in colleges and universities. This regulation shall not, however, exclude the certificates of two or more teachers, who may deliver conjointly, separate, perfect, and distinct courses on anatomy and physiology, and on the theory and practice of surgery.

Certificates shall not be received for attendance on lectures on anatomy and physiology, unless such lectures shall have been delivered upon at least five days of each week of the usual *winter* season, between October and May, nor on the theory and practice of surgery, unless delivered within the *same* period, on at least three days in each week.

The courses of lectures on the practice of medicine, chemistry, materia medica, midwifery, and medical jurisprudence, shall consist of sixty lectures at least,* and the courses of dissections and demonstrations shall be of six months' duration.

Certificates shall not hereafter be received for attendance on lectures delivered in Ireland, unless from persons who shall have acquired, either by education or practice, such ample information, on professional subjects generally, as is required from candidates for the Fellowship of the College, and who shall have enjoyed such opportunities of acquiring information on the particular subjects upon which they propose to lecture, as the Council may consider necessary to qualify them to perform that duty.

Returns of Students attending Lectures.—Professors and lecturers are required to transmit to the College on or before the 25th day of November in each year, returns of the names of the pupils who shall have entered to attend, and are then actually attending their respective lectures or demonstrations. They are also required to ascertain, from time to time, whether the students so returned are in attendance or not, as similar returns are required in the course of the session.

* The summer courses on these subjects are recognized.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

Qualifications, Examination, and Admission of Candidates for the Licence.

No Member or Licentiate of any company of apothecaries shall be admissible to the licence of the College; and should any such, after due examination, be approved of, he shall not be admitted as a Licentiate until he shall have surrendered his licence as an apothecary, and produced satisfactory evidence of his name having been removed from the list of the company. No person engaged in any kind of trade, shall be admitted to examination for the licence. Every candidate for the licence of the College, except those who have entered as students in arts, shall be required to produce a certificate of matriculation in the University of Dublin, conformably to the statute, 40 Geo. iii., c. 84, s. 34.

Candidates must produce evidence of having been engaged in the study of medicine for four years at least, and of having attended not less than two of the required courses in each year.

Candidates must produce evidence of having completed the following course of education,—viz., of having attended one or more courses of lectures on anatomy and physiology, chemistry, institutes of medicine, materia medica and pharmacy, midwifery and diseases of women and children, practice of medicine, and on surgery—each course to be of six months' duration; on botany and on medical jurisprudence for at least three months each; of having performed a course of dissections and attended the accompanying demonstrations during six months, and of having attended a course of practical chemistry for at least three months.

All the lectures are required to have been delivered by the respective Professors of the School of Physic in Ireland, or by other lecturers recognized by the College.

Candidates must produce certificates of attendance for two years and six months on the practice of a recognized hospital, and the clinical lectures delivered therein during that period; also for six months on the practice of a lying-in hospital recognized by the College.

Candidates who, on having performed the full acts, have graduated in medicine in one of the universities of Great Britain or Ireland, or who have been admitted as Licentiates of either of the Royal Colleges of Physicians of London or Edinburgh shall be admissible to examination on such qualification.

Candidates who have been Licentiates of a college of surgeons in the united kingdom for four years, or upwards, or who, in addition to their diploma as such, shall produce certificates of attendance on a course of lectures on botany and the institutes of medicine, and on the practice of a recognized lying-in hospital for six months, shall be admissible to examination on such qualifications. The examination of candidates for the licence of the College to practise medicine shall be conducted on two separate days: the subjects of examination for the first day shall be anatomy and physiology, botany, chemistry, and materia medica; for the second day, acute diseases, chronic diseases, the institutes of medicine, and midwifery.

Candidates who are graduates in medicine of one of the universities in Great Britain or Ireland, Licentiates of either of the Royal Colleges of Physicians, London or Edinburgh, or members of a royal college of surgeons in the united kingdom, being graduates in arts of the Universities of Dublin, Oxford, or Cambridge, shall be required to undergo the second day's examination alone,—botany and materia medica in the case of members of a college of surgeons being added thereto. The examinations shall be conducted in the English language; but every candidate, except graduates in arts of Dublin, Oxford, or Cambridge, may be required, at the option of the President, to translate from a Latin or Greek medical author before he is admitted to examination as to his professional acquirements. Fee for the licence, £30, in addition to the stamp duty.

Every candidate shall, previously to examination, sign

the following declaration:—"I, A. B., hereby authorize the President and Fellows of the King and Queen's College of Physicians in Ireland, to erase my name from the list of Licentiates, and I consent to surrender my licence, and to have my privileges as a Licentiate withdrawn, if I shall, after having obtained the licence from said College, either continue to be or become a Licentiate of any company of apothecaries; or if I shall at any time hold or have any interest in an apothecary's shop, or engage in any trade in any part of the united kingdom."

When the College shall not be satisfied with the answering of any candidate, it shall be in their power, if they think fit, to repeat the examination of either day, at an interval of not less than two months; and should he ultimately be rejected, the fees to the College, and the amount of stamp duty lodged with the treasurer, shall both be returned.

Every person who shall be admitted as a Licentiate of this College, shall upon such admission, and before he receives his licence, subscribe and promise the due fulfilment of the following declaration, viz.:—"I, A. B., do hereby solemnly and sincerely promise that I will observe the statutes and bye-laws of this College, and to my power endeavour that the honour of the College be preserved entire; and in all things that belong to the honour or profit thereof, I shall be ready to give my advice and assistance. I engage not to practise any system or method (so called) for the cure or alleviation of disease of which the College has disapproved; nor to endeavour to obtain practice or to attract public notice by advertising, or by any other unworthy means; I also engage that I will neither permit nor sanction the use of my name by any other party for such purposes, nor in connexion with any secret or other remedy; and in case of any doubt relative to the true meaning or application of this engagement, I promise to submit to the judgment of the College. I promise that in all things lawful and honest, I will be obedient to the President, Vice-President, and Censors of the College: and I solemnly and sincerely declare, that should I violate any of the conditions enumerated in this declaration, so long as I shall be either a Licentiate or Fellow of the College, I thereby render myself liable, and shall submit to any reasonable punishment, whether censure of the College, pecuniary fine (not exceeding twenty pounds), or expulsion and surrendering of the licence, whichever the President and Fellows of the College, or the majority of them, shall think proper to inflict."

The following shall be the form of the licence to be granted to every person examined and admitted to practise medicine by the College:—"Omnibus ad quos præsentes Literæ pervenerint, et quorum interest, sit notum, Nos Præsidem et Socios Collegii Medicorum Regis et Reginæ in Hibernia, ——— postquam semel iterumque examinatione solenni, coram nobis pro more institutâ, se doctum et in arte medica adprime versatum probasset, licentiam prædictæ artis exercendæ quamdiu se bene gesserit, legibusque hujus Collegii obtemperaverit, plene quantum in nobis est permisse; et auctoritate Regiarum Chartarum, nobis in istum finem concessarum confirmasse; et hoc, Sigillo Collegii suffixo, et nominibus subscriptis, testatum volumus. Datæ Dublinii."

Every member of this College who shall desire to obtain the licence to practise midwifery shall produce a certificate of attendance for six months on the practice of a recognized lying-in hospital, when the College shall proceed to examine him as to his knowledge of midwifery; and if approved of, they shall grant him a special licence as a practitioner in midwifery, and shall cause him to be designated as such in the authorized lists of the College.

All Licentiates of this College shall have permission to attend the meetings during the examinations for licence.

At all meetings of physicians of the College, where the President is present, precedency and all marks of honour shall be paid to him. To preserve a good understanding among the members of the College, every member shall consult with every other member who is not under the censure of the College; and whosoever shall at any time refuse so to do, shall be liable to the censure of the College. Any member of this College who is guilty of unprofessional conduct, either by advertising or other practices unbecoming the honourable profession of physic, shall be placed under the censure of the College. No member of this College shall consult with, or otherwise sanction any other member who is under censure; nor consult with, or sanction professionally, any person who by advertisement, or other unworthy means, endeavours to obtain practice, or to attract public notice. No member of the College shall consult with any person who, for the cure or alleviation of disease, uses any secret remedy, or adopts and practises any system or method of which the College has disapproved.

Forwarded by order of the President.

William Edward Steele, Registrar.

In reference to these new regulations of the College of Physicians, it is necessary to observe, that the "Certificate of Matriculation in the University of Dublin," required in the first paragraph, is merely a copy of an entry in a book, for which a student pays five shillings. It implies no academic matriculation, no examination, and confers no collegiate *status* of any kind. It is required to bring students, not of the University, attending the lectures of the medical professors within the control of the College authorities, with a view to the preservation of order. The seventh paragraph providing for the admission of Licentiates of Colleges of Surgeons, appears to be superfluous, if not intended to be an expression of opinion that surgeons should be in practice for four years to entitle them to become physicians. Licentiates of the College of Surgeons must possess qualifications much more extensive than those required for admission to the examination for the licence of the College of Physicians, and by those laws must therefore be admissible to examination, whether surgeons or not: the certificates of the professors of the College of Surgeons being received as qualification. The object of these regulations seems to be to open the College of Physicians to surgeons, and if these rules do not do so unequivocally, they should be amended.

UNIVERSITY OF DUBLIN—TRINITY COLLEGE.

MEDICAL DEGREES.

Two Degrees are granted by this University: one of *Bachelor* of Medicine, the other of full *Doctor;* and none but *Graduates in Arts* are admitted to either. For the Degree of *Bachelor of Medicine* four years' medical study are required, and attendance on the following courses—viz., anatomy and chirurgery, surgery, chemistry, practical chemistry, botany, and dissections—one of each, by the University professors; institutes of medicine, practice of medicine, and materia medica—one of each, by Sir Patrick Dun's professors in the School of Physic; midwifery and medical jurisprudence by the professors of the College of Physicians—one of each; clinical lectures in Sir Patrick Dun's Hospital—three consecutive courses of three months' duration; and attendance on a general hospital for nine months. Of the above lectures, at least *two*, and not more than *three*, must have been attended during each of the four years' medical study. Students in Arts, matriculated as medical students, and having their names on the College books, are permitted to attend one course of lectures delivered by the four University professors free of expense; but certificates available in other colleges are not granted to them.

From recently published announcements respecting medical graduation in this University, the standing at which the degrees of Bachelor and Doctor can be taken does not seem to be settled. By the old regulations *(Regulæ Universitatis)* the Bachelor's degree cannot be taken until

three years after graduation in arts, and that of full Doctor until five years after graduation as Bachelor of Medicine. By newer rules it appears, a candidate can graduate as Bachelor after four years, and as Doctor after seven years, from entrance. Medical students, unconnected with the University, are allowed to attend the lectures of the professors, and are required to enrol their names as matriculated medical students; but they are not admitted to any examination, or entitled to take any degree or other academic rank.

QUEEN'S UNIVERSITY IN IRELAND.

Candidates for the degree of M.D. in the Queen's University in Ireland, shall have passed the matriculation examination prescribed for students in the faculty of medicine in the Queen's Colleges, and shall have pursued, four years, the following courses of study, the order of which, although strongly recommended, is, however, not absolutely prescribed:—

In the first year.—One modern language, anatomy and physiology, chemistry,—six months. General physics, botany,—three months.

In the second year.—Anatomy and physiology, practical anatomy, materia medica,—six months. Practical chemistry, comparative anatomy,—three months.

In the third year.—Practice of surgery, midwifery, clinical surgery,—six months.

In the fourth year.—Practice of medicine, medical jurisprudence, clinical medicine,—six months.

Candidates for the degree of M.D. will be required further to give evidence of their having attended a general hospital recognized by the Senate, during twenty-four months, or such general hospital during eighteen months, and the out-practice of an hospital or dispensary for six months, and also a course of practical pharmacy during three months. Candidates shall have attended at least one-third of the above courses in the medical faculty of some one or other of the Queen's Colleges in Ireland, and for the remainder, authenticated certificates shall be received from the professors or lecturers in colleges or medical schools recognized by the Senate of the Queen's University in Ireland. Students in Arts of the Queen's Colleges shall be admitted to examination for the degree of M.D. after having obtained the degree of A.B., provided they shall have completed the curriculum prescribed above for the second, third, and fourth years of medical study. Every candidate, before being admitted to the degree of M.D., shall undergo an examination in all the subjects comprehended in the above course of education, and shall afford satisfactory evidence that he is twenty-one years of age.

ARMY MEDICAL SERVICE.

Inspector-General of Hospitals and Superintendent of the Medical Department—Dr. Andrew Smith.

Professional Assistant—Dr. Thomas Spence, Staff Surgeon of the First Class.

Inspector of Medicines and Instruments—Staff-Surgeon Pilleau, Second Class.

Apothecary to the Forces—F. M. Bassano.

Regulations, dated February, 1840.

Candidates are required to produce the diploma of the College of Surgeons of London, Edinburgh, or Dublin, and the following testimonials:—Eighteen months' attendance at an hospital where the average number of in-patients is not less than one hundred; twenty-four months' anatomy; twelve months' practical anatomy; twelve months' surgery, or (what is preferred) six months' surgery and six months' military surgery; eight months' clinical surgery; a complete course of two or three lectures during the week; twelve months' practice of physic, or six months' practice of physic, and six of general pathology; eight months' clinical lectures on ditto, the same as required in surgery; twelve months' chemistry; six months' practical chemistry; three months' botany; four months' materia medica; three months' practical pharmacy, or apprenticeship; five months' natural history; five months' midwifery.

The candidates must be unmarried, and not beyond twenty-six, nor under twenty-one years of age. A liberal education and a competent knowledge of Greek and Latin are indispensably requisite in every candidate. Although the British schools are specified, candidates who have received regular education in approved foreign universities or schools will be admitted to examination. With the exception of practice of physic and clinical medicine by one teacher, candidates must have attended separate lecturers for each branch of science. Before promotion from the rank of assistant-surgeon to any higher rank, every gentleman must be prepared for examination before a board of medical officers.

Diplomas, tickets of attendance on lectures, and certificates of regular attendance, must be lodged at the office at least one week before the candidate appears for examination; and likewise certificates of moral conduct and character, one of them by a clergyman, and that of the parochial minister, is desirable. Baptismal certificates are required; if the parish register cannot be resorted to, an affidavit from one of the parents, or some person who can attest the fact, will be accepted. The certificate of the teacher of practical anatomy must state the number of subjects or parts dissected by the pupil. All candidates for medical appointments are required to be conversant with Cullen's Nosology. Hearing and vision must be good, shortsighted persons are inadmissible, constitution must be sound, and bodily frame at least moderately robust.

Note.—All communications to be forwarded "unsealed," under cover, to "The Right Honourable the Secretary at War," with the words "Army Medical Department" at the corner.

NAVAL MEDICAL SERVICE.

Director-General of the Medical Department of the Navy—Sir William Burnett, K.C.B., K.C.H., M.D., F.R.S.

Regulations, dated August 1, 1850.

The Lords Commissioners of the Admiralty have directed "that no person be admitted as an *Assistant-Surgeon* in the Royal Navy, who shall not produce a certificate from one of the Royal Colleges of Surgeons of England, Edinburgh, or Dublin, or from the Faculty of Physicians and Surgeons of Glasgow, of his fitness for that office; nor as *Surgeon*, unless he shall produce a diploma, or certificate, from one of the said royal colleges or faculty, founded on an examination to be passed subsequently to his appointment of assistant-surgeon, as to the candidate's fitness for the situation of surgeon in the navy; and in every case the candidate producing such certificate, or diploma, shall also undergo a further examination before the Director-General of the Medical Department of the Navy, touching his qualifications in all the necessary branches and points of medicine and surgery for each of the steps in the naval medical service." Previously to the admission of assistant surgeons into the navy, it will be required that they produce proof of having received a preliminary classical education, and that they possess in particular a competent knowledge of Latin; also,

That they are of good moral character, the certificate of which must be signed by the clergyman of the parish, or by a magistrate of the district.

That they have served an apprenticeship, or have been engaged for not less than six months in practical pharmacy.

That their age be not less than twenty years; nor more than twenty-four years; and that they are unmarried.

That they have actually attended an hospital in London, Edinburgh, Dublin, Glasgow, Aberdeen, or Manchester, for two years subsequently to the age of eighteen, in which hospital the average number of patients is not less than 150.

That they have been engaged in actual dissections of the human body twelve months; the certificate of which from the teacher must state the number of subjects or parts dissected by the candidate.

That they have attended lectures, &c., on the following subjects, at established schools, by physicians or surgeons of the recognized colleges of physicians and surgeons, in the united kingdom, for periods not less than below stated; observing, however, that such lectures will not be admitted if the teacher shall lecture on more than one branch of science, or if the lectures on anatomy, surgery, and medicine, be not attended during three distinct winter sessions of six months each:—Anatomy, eighteen months; or general anatomy, twelve months, and comparative anatomy, six months. Surgery, eighteen months; or general surgery, twelve months, and military surgery, six months. Theory of medicine, six months; practice of medicine, twelve months. (If the lectures on the theory and practice of medicine be given in conjunction, then the period required is eighteen months.) Clinical lectures (at an hospital as above) on the practice of medicine, six months; on the practice of surgery, six months. Chemistry, six months; or lectures on chemistry, three months, and practical chemistry, three months. Materia medica, six months. Midwifery, six months, accompanied by certificates stating the number of midwifery cases personally attended. Botany, six months; or general botany, three months, and medical botany, three months.

N.B.—Six months' lectures on pathology, if given at a university where there may be a professorship on that branch of science, will be admitted in lieu of six months' lectures on the practice of medicine.

In addition to the tickets for the lectures, certificates must be produced from the professors, by whom the lectures were given, stating the periods (in months) *actually* attended by the candidates. The time also of actual attendance at an hospital or infirmary must be certified.

A favourable consideration will be given to the cases of those who have obtained the degree of M.D. at Oxford, Cambridge, Edinburgh, Dublin, Glasgow, London, or Aberdeen; or who, by possessing a knowledge of diseases of the eye, and of any branch of science connected with the profession, such as medical jurisprudence, natural history, natural philosophy, &c., appear to be more peculiarly eligible for admission into the service; observing, however, that lectures on these or any other subjects cannot be admitted as compensating for any deficiency in those required by the regulations.

By the rules of the service, no assistant-surgeon can be promoted to the rank of surgeon until he shall have served three years (one year of which must be in a ship actually employed at sea), and can produce a diploma from one of the before mentioned royal colleges, or the Faculty of Physicians and Surgeons, and it is resolved that not any diploma or certificate of examination from either of the aforesaid royal colleges shall be admitted toward the qualification for surgeon, unless the diploma or certificate shall be obtained on an examination passed after a period of not less than three years' actual service, observing that no one can be admitted to an examination before the Director-General for surgeon, unless, as hereinbefore mentioned, he can produce a diploma, together with the most satisfactory certificates, that he has performed, on the dead body, under the superintendence of a professor or teacher of known eminence, all the capital operations of surgery, and is perfectly competent to perform any operation with skill and dexterity, and thoroughly acquainted with the anatomy of the parts involved in such operation; without which qualification, no one hereafter can be promoted to the higher branches of the service, and whenever assistant-surgeons already in the service (whose professional education may not be in accordance with the above), obtain leave to study previously to their passing for surgeon, they will be required, on their examination, to produce testimonials of their having availed themselves of the period of leave to complete their education agreeably to these regulations generally.

Candidates who may be admitted into the naval medical service must serve in whatever ships, &c., they may be appointed to; and, in the event of their being unable to do so from sea-sickness, their names cannot be continued on the naval medical list, nor can they, of course, be allowed half-pay.

By an Admiralty Circular, dated July 17th, 1850, assistant-surgeons are to be divided into two classes. The first class to consist of all who have completed three years' servitude from the period of their first entry (one year of which must be served on board a commissioned ship, and the other two may be served in one of the naval hospitals), and who have passed their examination for surgeon either at home or abroad. "Assistant-surgeons, who have served more than three years, and have passed the examination for surgeon under the above conditions, are to rank next to naval instructors, and are to mess with the board-room officers, to be allowed cabins when the accommodation and space on board will admit." The second class of assistant-surgeons to consist of all those who have not served three years, and those who have not passed their examination for surgeon. First-class assistant-surgeons, who may be serving in small vessels commanded by lieutenants, are to mess in the guard-room with the other officers.

ORDNANCE MEDICAL DEPARTMENT.

Master-General—The Marquis of Anglesey.
Inspector-General—Mr. James Stewart.
Deputy-Inspector-General—Dr. Verling.

Provisional List.—Medical students who have completed their twentieth year, who have been well instructed in Latin and Greek, the elements of mathematics and natural philosophy, and who can produce satisfactory proofs of being diligent in the study of their profession, and the sciences connected with it, may be entered in the provisional list of gentlemen desirous of being admitted candidates for the Ordnance Medical Department. A knowledge of modern languages, though not indispensable at the time of provisional reception, is highly desirable, and will be duly appreciated.

Candidates.—No applicant is to be received on the list of candidates before he is twenty-two, nor retained on it after he is twenty-five years of age. The age of every individual must be verified by a certificate of his baptism, if it can be procured; but if not, by a solemn declaration of one of his parents, or of some other person who can attest the date of his birth.

Qualifications.—Every candidate must bring proof of having diligently served five years to a surgeon and apothecary, if educated in England; but if not, qualification in the practice of medicine and pharmacy equivalent thereto.

Of having attended the practice of surgery in a recognized hospital or hospitals, where clinical instruction is constantly given for three years, three months being allowed for a vacation in each year. Of having attended:—Anatomical lectures, demonstrations, dissections, three anatomical seasons or sessions; morbid anatomy and pathology, one course; lectures on the principles and practice of surgery, delivered in two distinct periods or sessions, two courses, each comprising seventy lectures; or one course of surgery and one of military surgery; natural history or comparative anatomy, one course; chemistry, one course of 100 lectures; botany, one course; materia medica and therapeutics, one course of 100 lectures; lectures on the principles and practice of medicine, two courses, each 100 lectures, second and third winters; medical practice, with clinical lectures, eighteen months, commencing the second session—viz., twelve months in a recognized hospital and the remaining six months either in a recognized hospital or a dispensary; medical jurisprudence, with toxicology, one course of fifty lectures; midwifery, two courses, each of sixty lectures, second and third sessions; practical midwifery (not less than thirty cases); after the conclusion of the first course on midwifery lectures, a certificate of having passed the usual examination is to be produced; diseases of the eye (with attendance on patients of that class), one course.

He must produce a diploma from either of the Colleges of London, Edinburgh, or Dublin; and if not, a graduated M.D. of Scotland or Ireland, after having actually passed an examination in the university where he has obtained his degree; a certificate also of qualification from the Society of Apothecaries in London. It is likewise expected that candidates shall have attended establishments for the cure of diseases of the ear and skin, and for the treatment of patients affected with mental derangement.

The moral conduct and character of each individual must be certified by the gentleman to whose care his education was confided, and also by a clergyman, who, if practicable, should be the incumbent or officiating minister of the parish in which the applicant usually resides. The candidate is required to sign, before the board that is appointed to examine him, and to report upon his professional qualifications, a *Declaration* to the effect that he has no complaint whatever which can interfere with the effective performance of his duty; that he is unmarried; that he enters upon his duties with a full conviction of their importance, and will endeavour thoroughly to fulfil them.

EAST INDIA MEDICAL SERVICE.

Commander—Lieutenant-Colonel Hay.
Surgeons—Dr. Jackson and Mr. Westall.
Public Examiner and Inspector—Major-Gen. Pasley.
Clerk for passing Cadets and Assistant-Surgeons—Mr. Clarke.
Examining Medical Officer—Dr. Scott.

Regulations.

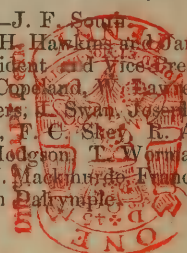
Age.—The assistant-surgeon must not be under twenty-two years, in proof of which he must produce an extract from the register of the parish in which he was born, or his own declaration and other certificates agreeably to forms to be obtained in the East India House for cadets and assistant-surgeons.

Qualification in Surgery.—The assistant-surgeon, upon receiving a nomination, will be furnished with a letter to the court of examiners of the Royal College of Surgeons, to be examined in surgery; or should the assistant-surgeon be previously in possession of a diploma from the Royal College of Surgeons of London, or of the Colleges of Surgeons of Dublin, or Edinburgh, or of the College and University of Glasgow, or of the Faculty of Physicians and Surgeons of Glasgow, either of them will be deemed satisfactory as to his knowledge of surgery, without any further examination. He is also required to produce a certificate from the cupper of a public hospital in London, of being capable of practising, with proper dexterity, the art of cupping.

Qualification in Physic.—The assistant-surgeon will also be required to pass an examination by the Company's examining physician in the practice of physic, as much anatomy and physiology as is necessary, and the art of prescribing and compounding medicines; and he will be required to produce proof of his having attended at least two courses of lectures on the practice of physic; and a certificate of having attended diligently the practice of the physicians at some general *hospital* in London (within the united kingdom) for six months, provided such provincial hospital contain at least, on an average, one hundred in-patients, and have attached to it a regular establishment of physicians as well as surgeons. No attendance on the practice of a physician at any *dispensary* will be admitted.

ROYAL COLLEGE OF SURGEONS, ENGLAND.

President—J. F. South.
Vice-Presidents—Cæsar H. Hawkins and James Luke.
The Council—The President and Vice-Presidents, R. Keate, G. J. Guthrie, T. Copeland, W. Lawrence, Sir B. C. Brodie, Bart., B. Travers, H. Swan, Joseph H. Green, E. Stanley, J. M. Arnott, F. C. Skey, R. A. Stafford, Bransby B. Cooper, J. Hodgson, T. Wormald, George Pilcher, John Bishop, G. W. Mackmurdo, Francis Kiernan, William Coulson, and John Dalrymple.



Court of Examiners—The President and Vice-Presidents, R. Keate, G. J. Guthrie, W. Lawrence, B. Travers, E. Stanley, J. H. Green, J. M. Arnott.
Professor of Anatomy and Physiology—J. Paget, Esq.
Hunterian Professor and Conservator of Museum—R. Owen, Esq.
Assistant-Conservator—J. T. Quekett, Esq.
Secretary—Mr. E. Belfour.

Regulations of the Council (1849) *respecting the Professional Education of Candidates for the Diploma of Member of the College.*

I. Candidates will be required to produce the following certificates—viz.: 1. Of twenty-one years of age. 2. Of having been engaged during four years in the acquirement of professional knowledge. 3. Of having studied practical pharmacy during six months. 4. Of having attended at a recognized hospital or hospitals in the united kingdom the practice of physic during one winter* and one summer† session. 5. Of having attended, during three winter and three summer sessions, the practice of surgery at a recognized hospital or hospitals in the united kingdom. 6. Of having studied anatomy and physiology, by attendance on lectures and demonstrations, and by dissections, during three winter sessions. 7. Of having attended, during two winter sessions, lectures on the principles and practice of surgery. 8. Of having attended, during one summer session, lectures on materia medica and lectures on midwifery; practical midwifery to be attended at any time after the conclusion of the session. 9. And of having attended one course of lectures on the practice of physic and one course on chemistry. [The course of study hereby prescribed is required to be observed by candidates who shall have pursued their studies in hospitals and schools in England. And those candidates who shall have studied in Ireland or Scotland will be admitted to examination upon producing certificates of having attended the required courses of lectures as delivered in the schools of Ireland and Scotland.]

II. Members or Licentiates of any legally constituted college of surgeons in the united kingdom, and graduates in surgery of any university requiring residence to obtain degrees, will be admitted for examination on producing their diploma, licence, or degree, together with proof of being twenty-one years of age, and of having been occupied at least four years in the acquirement of professional knowledge.

III. Graduates in medicine of any legally constituted college or university, requiring residence to obtain degrees, will be admitted for examination on adducing, together with their diploma or degree, proof of having completed the anatomical and surgical education required by the foregoing regulations, either at the school and hospital of the university where they shall have graduated, or at one or more of the recognized schools and hospitals in the united kingdom.

IV. Candidates who shall have attended at recognized colonial hospitals and schools,‡ the medical and surgical practice and the several courses of lectures, with the demonstrations and dissections required by the foregoing regulations, will be admitted for examination upon producing certificates of such attendance, together with certificates of having attended in London, during one winter session, the surgical practice of a recognized hospital, and lectures on anatomy, physiology, and surgery, with demonstrations and dissections.

V. Certificates will not be recognized from any hospital

* The winter session comprises a period of six months, and in England commences on the 1st of October and terminates on the 31st of March.

† The summer session comprises a period of three months, and in England commences on the 1st of May, and terminates on the 31st of July. No provincial hospital will be recognized by this college which contains less than 100 patients; and no metropolitan hospital which contains less than 150 patients.

‡ The recognition of colonial hospitals and schools is governed by the same regulations as apply to the recognition of provincial hospitals and schools in England.

unless the surgeons thereto be members of one of the legally constituted colleges of surgeons in the united kingdom; nor from any school of anatomy and physiology, or midwifery, unless the teachers in such school be members of some legally constituted college of physicians or surgeons in the united kingdom; nor from any school of surgery, unless the teachers in such school be members of one of the legally constituted colleges of surgeons in the united kingdom.

VI. Certificates will not be received on more than one branch of science from one and the same lecturer; but anatomy and physiology, demonstrations and dissections, will be respectively considered as one branch of science.

VII. Certificates will not be received from candidates who have studied in London, unless they shall have registered their tickets at the College, as required by the regulations, during the last ten days of January, March, and October in each year; nor from candidates who have studied elsewhere, unless their names shall duly appear in the registers transmitted during such studies from their respective schools.—By order of the Council,

EDMUND BELFOUR, Secretary.

N.B.—In the certificates of attendance on hospital practice and on lectures, it is required that the dates of commencement and termination be clearly expressed; and no interlineation, erasure, or alteration will be allowed. Blank forms of the required certificates may be obtained on application to the secretary, to whom they must be delivered, properly filled up, ten days before the candidate can be admitted to examination; and all such certificates are retained at the College.

REMARKS ON THE FOREGOING.

Candidates for the London diploma are not required to produce any proof of preliminary, classical, or other education; neither are they examined in the practice of medicine or in pharmacy. The diploma of the College is strictly and exclusively a surgical one, and does not profess to be a qualification for general practice. To become what is called a general practitioner; that is, to practise medicine, surgery, and midwifery, and to supply medicines to patients, the licence of the *London* Apothecaries' Company is necessary; but neither this, nor any other apothecary's licence, qualifies to practise medicine in Ireland.

SCOTCH AND ENGLISH MEDICAL COLLEGES.

We have not space for notice of these institutions in this day's publication. We, however, insert the following because it is the only one of them which has adopted the obvious measure of admitting regularly educated surgeons to examination without compelling them to live in the town where the College is situated for a year, or to pay for another "batch of certificates":—

UNIVERSITY OF ST. ANDREW'S.

Regulations of the Senatus Academicus respecting the Education of Candidates for the Degree of Doctor of Medicine.

I. Every candidate for a diploma in medicine, upon presenting himself for examination, shall produce satisfactory evidence—1. Of unexceptionable moral character. 2. Of having had a liberal and classical education. 3. Of having completed the twenty-first year of his age.

II. Fellows, Members, and Licentiates of the Royal Colleges of Surgeons of England, Edinburgh, and Dublin—of the Royal College of Physicians of London—of the Faculty of Physicians and Surgeons of Glasgow—and of the London Apothecaries' Company, *are eligible as candidates for the degree of Doctor of Medicine, on producing their diploma or licence.*

III. Candidates not holding any of the qualifications enumerated in the above clause, must produce satisfactory proof that they have regularly attended lectures delivered by professors in some university, or by fellows of the Royal Colleges of Physicians or Surgeons of London, Edinburgh, or Dublin, for four complete winter sessions, or for three winter and three summer sessions, on the following branches: Anatomy, two courses of six months each; practical anatomy or dissections, twelve months; physiology, one course of six months; chemistry, one do. do.; practical chemistry, one do. of three months; materia medica and pharmacy, one do. do.; midwifery and diseases of women and children, one do. do.; surgery, one do. of six months; clinical surgery, one do. do.; practice of medicine, one do. do.; clinical medicine, one do. do.; and that they have diligently attended for at least two entire years the medical practice in some public hospital in Great Britain or Ireland, containing at least one hundred beds, and having a regular establishment of physicians as well as surgeons.

MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, OCTOBER 29, 1851.

We have, as on similar occasions heretofore, to trespass on our subscribers for the use of a number of THE PRESS, to give currency to the annual announcements respecting education. Although not containing the usual weekly record of contributions to medical knowledge, it is not, however, without its value as an index of the component ingredients of this department, which exercises so much influence on the destinies of our profession. The practitioner in the most remote part of Ireland will take a hint from it; reminding him, as it does, of the probable quality of the additions to our ranks, from which his future fellow-labourers or competitors are to be derived. Such a display suggests many considerations, and demands careful comments, in which our space does not permit us now to indulge, but which we may presently make. The educational additions and improvements made within the year, have not been inconsiderable or unimportant, and therefore demand our serious attention.

THE MEDICAL COMMISSIONER.

As we predicted in our last, this event, so anxiously looked for, has taken place, and, as we anticipated, Dr. MACDONNELL, Professor of Descriptive Anatomy in the College of Surgeons, and one of the Surgeons to the Richmond Hospital, has been appointed; and we can, without disparagement to the other candidates for the office, congratulate our brethren on the selection. Dr. MACDONNELL is the son of a worthy, highly-respected, and distinguished physician, the late Dr. MACDONNELL of Belfast; and is himself, as a member of our profession, fully entitled to fill the important office to which he has been nominated. This is perhaps enough to say on the subject, were we not called on to express thanks on the part of the body to which we belong for the respect paid to their opinions by the government on this occasion. They felt that this office should be filled by a gentleman of respectability and integrity, and they have not been disappointed. It now only remains to appoint the Inspectors, and we have every reason to believe that this will be done with the same regard for the public service and the character of our profession. We have heard many names mentioned, and we think we could with safety point out two upon whom the choice will probably fall: one, a surgeon of standing in this city who has heretofore been engaged in similar duty, and who has given ample proofs of practical acquaintance with the subject; the other, an equally eligible provincial practitioner. We must, however, refrain from more particular allusion to the subject.

ROYAL COLLEGE OF SURGEONS IN IRELAND,

List of gentlemen who obtained the Diploma of the College during the present year:—

Henry Banks, Wicklow
Wm. J. Ingham, Belturbet
J. J. E. Jacob, Maryborough
William H. Woods, Dublin
Francis W. Knox, Ballina
John Morgan, Dublin.
G. P. Woodward, Dublin
John K. Leet, Dalkey
Wm. Rogan, Londonderry
John Carroll, Virginia
William Gordon, Co. Down
William C. Shaw, Killyleagh
Robert Macdonnell, Dublin
John Dunlop, Ballycastle
Edward A. Brien, Dublin
M. O'Connor, Ballylongford
Edward J. Morris, Miltown Malbay
James M. Barry, Kingstown
Charles H. Hardy, Dublin
David L. Finlay, Dublin
Stuart Moore, Dublin
Henry Harkan, Dublin
James J. Armstrong, Dublin
G. St. G. Tyner, Lucan
T. Dolan, Drumshambo
Edward Y. Kellett, Drumroo
George H. Halpin, Wicklow
Robert Mack, Lisburn
Robert Murray, Monaghan
Robert Fitzmaurice, Listowel
R. Wm. Jackson, Edenderry
Patrick Kane, Tralee
Michael Flynn, Dungarvan
John S. Bush, Dublin
Samuel Hill, Ballinderry
James Wallace, Omagh
Arthur E. Jacob, Maryboro'
John O'Sullivan
W. P. D'Alton, Ballynakill
G. A. Moorhead, Tullamore
Irving Bagnell, Durrow
John Williams, Macroom.

UNIVERSITY OF ST. ANDREW'S,

The list of gentlemen who obtained the decree of Doctor of Medicine at the University of St. Andrew's, we are compelled to hold over. It will appear in our next.

Sold by all Booksellers, price 12s.,

ELEMENTS OF MATERIA MEDICA:

Containing the Chemistry and Natural History of Drugs, their Effects, Doses, and Adulterations, with the Preparations of the Pharmacopœias.

By Dr. FRAZER,

Licentiate of the King and Queen's College of Physicians, and Royal College of Surgeons, Ireland; Lecturer on Botany and Natural History to the Carmichael School of Medicine.

J. LAMPREY,
29, Westmorland-street.

MANUFACTURING CUTLER,

Begs to call the attention of the Medical Students to his Stock of Superior Dissecting and Pocket Instruments, which will be found most satisfactory in use and moderate price.

N.B.—Every description of Surgical Instruments made and repaired.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

At the stated Meeting of the College, held on St. Luke's Day, the following Officers were Elected for the ensuing year:—

President—Dr. William F. Montgomery.
Vice-President—Dr. Aquilla Smith.
Censors—Drs. Aquilla Smith, Henry Kennedy, Robert Travers, John Ringland.
Treasurer—Dr. John Mollan.
Librarian—Dr. George Alexander Kennedy.
Inspectors of Apothecaries' Shops—The Censors.
Professor of Midwifery—Dr. W. F. Montgomery.
Professor of Medical Jurisprudence—Dr. Thomas Brady.

WILLIAM EDWARD STEELE, M.B.,
Registrar, 15, Hatch-street.

October 18, 1851.

DR. STEEVENS' HOSPITAL.

The Winter Session and Clinical Lectures will commence on Monday, the 3rd of November.

Visiting hour, eight o'clock a.m.

Terms of attendance on the Medical and Surgical Wards, Lectures included:—

Winter six months	...	Eight guineas.
Summer do.	...	Five guineas.
Intern Dressership:—		
Winter six months	...	Twenty guineas.
Summer do.	...	Fifteen guineas.

This hospital receives two hundred patients, and is provided with distinct wards for Venereal Patients, and also affords the accommodation of an extensive Medical Library.

QUEEN'S UNIVERSITY IN IRELAND.

QUEEN'S COLLEGE BELFAST.—SESSION 1851–52.

FACULTY OF MEDICINE.

Lectures will commence on Tuesday, November 4.

Anatomy and Physiology—Dr. Carlisle.
Practice of Medicine—Dr. Ferguson.
Practice of Surgery—Dr. Gordon.
Chemistry—Dr. Andrews.
Materia Medica—Dr. Stewart.
Midwifery—Dr. Burden.
Comparative Anatomy—Dr. Carlisle.
Anatomical Demonstrations—Dr. Murney.

Practical Anatomy under the superintendence of the Professor of Anatomy and Physiology, the Demonstrator of Anatomy, and the Anatomical Assistant.

Practical Chemistry under the superintendence of the Professor of Chemistry and his Assistant.

Clinical Lectures will be given during the session at the Belfast General Hospital by the attendant physicians and surgeons; certificates of attendance on which are received as qualifications by the Senate of the Queen's University, and by the various licensing boards.

No student will be allowed to enter for any of the winter courses later than the 25th of November.

For further information see the Belfast Queen's College Calendar for 1851; or apply to the Registrar of the College.

By order of the President,
W. J. C. ALLEN, Registrar.

MEATH HOSPITAL AND COUNTY OF DUBLIN INFIRMARY.

The Winter Session commenced on the 1st of October. The usual courses of Clinical Instruction will commence on the first Monday in November, and will be continued through the session by the Physicians and Surgeons of the Institution.

Arrangements have been made to prevent the hours of attendance and lectures from interfering with any other place of instruction in Dublin.

The Medical and Surgical Clinical Instruction will be carried on on the alternate days—Mondays, Wednesdays, and Fridays for SURGICAL; and Tuesdays, Thursdays, and Saturdays for MEDICAL Instruction.

Operations, unless in cases of emergency, will only be performed on the days of Surgical Instruction.

A Surgical Registry of all cases admitted into the hospital is carefully preserved, and is open to the inspection of the pupils. A dispensary is attached to the hospital, in which the pupils are allowed to perform all the minor operations in surgery, under the guidance of the attending Surgeons. From 200 to 300 patients are prescribed for and relieved in the dispensary daily.

The following premiums are to be awarded, as usual, at the close of the session:—

1. The Clinical Medical Premiums.
2. The Clinical Surgical Premiums.
3. The Stethoscopic Prizes.

Of these there are two in each class to be awarded according to the order of merit.

The situation of Resident Pupil is open to pupils as well as apprentices of the hospital.

Special recommendatory certificates are given to such gentlemen as have filled the situation of Clinical Practising Assistants in the hospital for at least four months to the satisfaction of the medical officers.

Certificates of attendance on this hospital are acknowledged all over the empire.

The hospital is only a few minutes walk from the College of Surgeons.

The Medical Clinical Instruction is given by Dr. Stokes, Regius Professor of the Theory and Practice of Physic, Trinity College, Dublin, &c.; and Dr. Lees, Fellow of the College of Physicians, Lecturer on the Practice of Physic, Examiner in Medicine to the Queen's University in Ireland, &c.

The Surgical by Sir P. Crampton; Mr. G. Porter, A.M., F.R.C.S.I., &c.; Mr. Porter, A.M., Professor of Surgery, Royal College of Surgeons, &c.; Mr. Collis, A.M., F.R.C.S.I.; Mr. Smyly, A.M., F.R.C.S.I., &c.; and Mr. Rynd, A,M., F.R.C.S.I., &c. &c.

A Course of Lectures on Operative Surgery will be delivered in the course of the session by Sir Philip Crampton.

For further particulars apply to Francis Rynd, Esq., Secretary, No. 19, Ely-place, or at the hospital.

SCHOOL OF SURGERY, ROYAL COLLEGE OF SURGEONS.

The Session 1851–52 commenced on Monday, October 27, at one o'clock.

Anatomy and Physiology—Dr. Jacob.
Descriptive Anatomy—Dr. Hart and Dr. Macdonnell.
Surgery—Mr. Porter and Mr. Hargrave.
Practice of Medicine—Dr. Benson.
Chemistry—Dr. Barker.
Midwifery—Dr. Beatty.
Comparative Anatomy—Dr. Jacob.
Dissections by the Professors of Anatomy and the Demonstrators—Dr. Leeson, Mr. Labatt, Mr. T. D. Hargrave, Mr. Malcolmson, and Mr. Morgan.

Commencing May 3, by order of the College.

Materia Medica—Mr. Williams.
Medical Jurisprudence—Dr. Geoghegan.
Botany—Dr. A. Mitchell.
Practical Chemistry—Dr. Barker.

The Fee for each of the above Courses is Two Guineas, except Comparative Anatomy, which is free.

A Public Course of Lectures on Comparative Anatomy and Zoology, free to all students, is delivered by the Professor of Anatomy and Physiology at the commencement of the session; and additional lectures on the same subject at intervals during the winter.

Practical Instruction in Operative Surgery is given by the Professors of Surgery, separate from the Surgical Lectures. Fee, £5 5s.

The Professor of Chemistry receives operating pupils into the Chemical Laboratory.

The Professor of Medical Jurisprudence gives practical instruction in Toxicology in his Laboratory.

The following Ordinance was made by the Council of the College on the 9th of April, 1851:—"To enable surgical students to devote more time to hospital attendance and dissection during the winter session, the lectures on materia medica, medical jurisprudence, practical chemistry, and botany, shall be delivered during the summer session in the School of the College, and in the schools recognized by the College; and certificates granted subsequent to the 30th of April, 1851, shall not be received as qualification for letters testimonial, unless issued in conformity with this regulation." Similar regulations have been adopted by the Council of the College of Surgeons of England

In order to give full effect to this order, and to secure the advantages contemplated by it, no lectures will be delivered during the winter before one o'clock; from which hour the order of business will be as follows:—

Descriptive Anatomy, at one o'clock every day.
Anatomy and Physiology, at two o'clock every day.
Surgery, at three o'clock on Tuesdays, Thursdays, and Saturdays.
Chemistry, at three o'clock on Mondays, Wednesdays, and Fridays.
Practice of Medicine, at four o'clock on Mondays, Wednesdays, and Fridays.
Midwifery, at four o'clock on Tuesdays, Thursdays, and Saturdays.

Dissections from sunrise to sunset; one or more of the Demonstrators being always present to give instruction.

The Anatomical Instruction on Mondays, from one to three o'clock, will consist of practical instruction in the use of the Microscope, Minute Dissections of Organic Structure, and the making of Anatomical Preparations.

The Professor of Botany will commence a course of Lectures on Structural and Physiological Botany in February. This course, taken in conjunction with that on Comparative Anatomy and Zoology, by the Professor of Anatomy and Physiology, constitutes the Course of Natural History required by the Army Medical Board.

Pupils attending the Lectures on Midwifery and Diseases of Women and Children are admitted to the practice of a recognized midwifery hospital on payment of a fee of £4 4s.

CITY OF DUBLIN HOSPITAL,

Upper Baggot-street.

The Winter Session commenced on Monday, October 27th.

During the summer recess this Hospital has been greatly enlarged. Its arrangements are now such as to afford the student an opportunity of studying disease in all its forms—medical and surgical. The morning visit commences daily at half-past eight o'clock, when the nature, treatment, and progress of each case are explained at the bedside of the patient, and ample opportunity afforded to every student of becoming practically acquainted with the uses of the Stethoscope. Clinical Lectures are also delivered after the hospital visit.

Connected with the hospital is an extensive Dispensary, at which the pupils are allowed to perform the minor operations, under the guidance of the surgeons, and are rendered familiar with the details of dispensary management.

Every facility is given to students desirous of acting as Dressers and Clinical Assistants, subsequent to which all pupils of the hospital are eligible to the situation of House-Surgeon, according to merit.

A distinct Course of Lectures upon Diseases of the Eye is delivered by Dr. Jacob, and special wards are appropriated for the reception of Eye cases. Extended opportunities are thus afforded for acquiring a thoroughly practical knowledge of this important subject.

A ward is appropriated to the Diseases of Females, and clinical instruction is given upon all forms of Uterine Affection by Dr. Beatty.

Mr. Tufnell's Course of Lectures upon Military Surgery is also open to the pupils of the hospital. This Course is recognized in the professional qualification of candidates for admission into the Army, Navy, and Ordnance Medical Departments.

A Lending Library of well chosen books has been provided for the use of the pupils; and a correct registry of the cases in hospital is kept by the house-surgeon, to which they have free excess.

Certificates of attendance at this hospital are recognized by all the Colleges, Universities, and Halls, and by the Army and Navy Medical Boards.

Fee for Winter six months ... ... Six guineas.
" Summer six months ... ... Four guineas.
" Nine months ... ... Eight guineas.

Physicians and Surgeons.

A. Jacob, M.D., F.R.C.S., Professor of Anatomy and Physiology, Royal College of Surgeons.
T. E. Beatty, M.D., F.R.C.S., Professor of Midwifery, Royal College of Surgeons.
C. Benson, M.D., F.R.C.S., Professor of the Practice of Medicine, Royal College of Surgeons.
W. Hargrave, M.D., F.R.C.S., Professor of Surgery, Royal College of Surgeons.
R. C. Williams, M.D., F.R.C.S., Professor of Materia Medica, Royal College of Surgeons.
T. G. Geoghegan, M.D., F.R.C.S., Professor of Forensic Medicine, Royal College of Surgeons.
J. Tufnell, Esq., F.R.C.S., Surgeon to the Military Prison.

Consulting Physicians.

Sir Henry Marsh, Bart., and Professor Apjohn.

Consulting Surgeons.

Sir Philip Crampton, Bart., Professor Porter, and J. W. Cusack, M.D.

For further particulars apply to Dr. Benson, 34, York-street.

PRACTICE OF PHYSIC.

Dr. Benson will commence the Course of Lectures on the Principles and Practice of Physic in the Royal College of Surgeons on Friday, the 9th day of November, at four o'clock p.m.

The Description, Pathology, Diagnosis, and Treatment of *Medical* Diseases will form the subject of the Course.

Pathological preparations, plates, and recent specimens of diseased parts, will be exhibited for the purpose of illustration.

The Lectures will be delivered on Mondays, Wednesdays, and Fridays throughout the session, at four o'clock.

N.B.—Gentlemen entering the Army are required to attend Two Courses of Lectures on the Practice of Medicine; and those entering the Navy to attend Three such Courses.

Fee for each Course ... ... Two guineas.

DISEASES OF THE EYE.

DR. JACOB will deliver a full Course of Lectures on the Anatomy, Physiology, and Optical Mechanism of the Eye, during the ensuing Session, in the College of Surgeons, and also a separate Course on its Pathology and Diseases, with the Operations required in their Treatment, in the City of Dublin Hospital.

THE

RICHMOND SURGICAL, WHITWORTH MEDICAL,

AND

HARDWICKE FEVER HOSPITALS,

North Brunswick-street.

The course of attendance and Clinical Lectures at the above mentioned hospitals will commence on Saturday, the 1st of November, 1851, at ten o'clock a.m., when Dr. Corrigan will deliver the Introductory Lecture. The Course will be continued during the Winter and Summer Sessions.

These hospitals contain 300 beds, and have attached to them the Talbot General Dispensary, the Lunatic Asylum at Island Bridge, and the Truss Establishment for the Relief of the Ruptured Poor of Ireland; also a well-selected Medical and Surgical Library.

There is also an extensive Museum, containing nearly four thousand Morbid Preparations, Casts, and Drawings, available for clinical instruction, and accessible to the hospital class at all times.

The Surgeons visit daily at half-past eight o'clock, and the Physicians daily at ten o'clock a.m.

Two Surgical and two Medical Clinical Lectures will be delivered in each week.

The resident pupils and clinical clerks of the Richmond, Whitworth, and Hardwicke Hospitals are selected from the class according to merit.

Two prizes will be given at the end of the Winter Session—one in Clinical Surgery, and one in Clinical Medicine.

The instruction in Clinical Medicine is given by—

Dr. Corrigan, M.R.I.A., Physician in Ordinary to the Queen in Ireland, Lecturer on the Practice of Medicine in the Carmichael School of Medicine, &c.;
Dr. Banks, M.R.I.A., Honorary Fellow of the King and Queen's College of Physicians in Ireland, King's Professor of the Practice of Medicine;
Dr. McDowel, F.R.C.S.I., Lecturer on Anatomy and Physiology in the Carmichael School of Medicine, &c.;
Dr. Gordon, F.R.C.S.I., M.R.I.A., Physician to the Government Lunatic Asylum at Island Bridge.

The instruction in Clinical Surgery is given by—

Dr. Hutton, M.R.I.A., Vice-President of the Royal College of Surgeons in Ireland, Surgeon to Simpson's Hospital, &c.;
Dr. Adams, F.R.C.S.I., M.R.I.A., &c.;
Dr. MacDonnell, F.R.C.S.I., M.R.I.A., Professor of Practical and Descriptive Anatomy in the Royal College of Surgeons in Ireland, &c.;
Mr. Hamilton, F.R.C.S.I., M.R.I.A., Examiner in Surgery to the Queen's University, Lecturer on Surgery in the Carmichael School of Medicine, &c.;
Dr. R. W. Smith, F.R.C.S.I., M.R.I.A., Professor of Surgery in the University of Dublin.

In the immediate vicinity of these hospitals is the Carmichael, late the Richmond Hospital, School of Medicine, where regular courses of lectures are delivered on the several subjects of medical science.

Attendance for nine months on the practice of a General Hospital, with attendance on the Clinical Lectures on Medicine and Surgery therein delivered, is, by a recent regulation of the Board of Trinity College, required from candidates for the degree of M.B.

The London College of Surgeons require a list of the pupils entering for the Winter Session, to be transmitted to their Secretary, on or before the 25th of November next.

Terms of Attendance.

For the Winter Session of six months, ... Eight guineas.
For the Summer Session of three months, Three guineas.

For further particulars apply to the Secretary, Dr. Hutton, 29, Gardiner's-place, or at the hospitals.

JERVIS-STREET HOSPITAL, DUBLIN.

The Winter Session for 1851–52 begins on the first day of November.

The hospital, which contains eighty beds, will be visited daily at nine o'clock a.m., and arrangements have been made to prevent the hours of attendance and lectures from interfering with any other place of instruction in Dublin. An extensive Dispensary is attached, in which the pupils are allowed to perform all the minor operations in surgery, under the guidance of the attending surgeons; and two wards have been recently fitted up for the treatment of Diseases of the Eye.

Two Medical and two Surgical Clinical Lectures will be delivered weekly by the attending physicians and surgeons; and due notice of operations will be given, unless in cases of emergency.

The situation of Resident Pupil is open to pupils as well as apprentices of the hospital, and the election for the ensuing session will take place by public examination on Monday, November 10th, at ten o'clock a.m.

Certificates of attendance at this hospital are recognized by the King and Queen's College of Physicians, the Queen's University, the University of Edinburgh, the Army Medical, Navy, and East India Boards, and by all the licensing bodies in the kingdom.

In addition to the ordinary Clinical Instruction, special Courses of Lectures will be delivered during the ensuing session on Diseases of the Skin by Dr. Neligan; on Diseases of the Eye by Mr. Ellis; and on Syphilitic Diseases by Dr. Stapleton; for all of which distinct certificates will be given.

Physicians.

J. Moore Neligan, M.D., M.R.I.A.. Lecturer on the Practice of Medicine in the Dublin School of Medicine.
John Hughes, L.K. and Q.C.P., and R.C.S.I., one of the Medical Officers of the Richmond Lunatic Asylum.

Surgeons.

R. P. O'Reilly, F.R.C.S.I.
Andrew Ellis, F.R.C.S.I., Professor of Surgery to the Apothecaries' Hall, Dublin.
M. H. Stapleton, M.D., M.R.I.A., F.R.C.S.I., Professor of Anatomy to the Royal Hibernian Academy.
R. Harrison, M.D., M.R.I.A., F.R.C.S.I. and E., Professor of Anatomy and Physiology, Trinity College, Dublin.
A. Banon, M.D., F.R.C.S.I., Medical Attendant of the Richmond Government Prison.
James S. Hughes, M.D., F.R.C.S.I.
J. H. Power, M.D, F.R.C.S.I., Lecturer on Surgery in the Carmichael, formerly Richmond Hospital, School of Medicine.

For further particulars apply to Mr. Macgrath, at the hospital, or to any of the physicians or surgeons.

LYING-IN HOSPITAL,

Rutland-square, Dublin.

This Hospital, established by Royal Charter of Geo. II., 1756, contains 140 beds, 15 of which are appropriated to the diseases of females. Upwards of 2000 women are annually delivered in this institution by the pupils, under the superintendence of the resident medical officers.

There is a Museum and Library for the use of the students, and comfortable accommodation for *intern* pupils.

This hospital is recognized as a School for the delivery of Lectures on Midwifery by the Master, by the Royal Colleges of Surgeons in England and Ireland, the Apothecaries' Hall of Dublin, and all other licensing bodies.

The Winter Course of Lectures begins in November, the Summer in May.

Application to be made to the Master, Dr. Shekleton, at the hospital.

THE [illegible] AND DOUBLE-ACTIONED PATENT TRUSS.

Invented by FRANCIS L'ESTRANGE, Esq., F.R.C.S.I.

WILLIAM DUFF, of 37, Molesworth-street, Dublin, calls the attention of the medical profession and the public to this Truss. He can state with confidence it is the only instrument constructed on scientific principles, having for its object the Radical Cure of Rupture. It acts not merely as a palliative, but will produce a radical cure, as is attested by numerous certificates.

W. D. is the only Manufacturer of the Instrument. The trade and public institutions will be liberally dealt with.

ST. VINCENT'S HOSPITAL,

Stephen's-green.

The Winter Session for the attendance of pupils on the practice of this hospital will commence on Saturday, 1st of November, 1851.

The hospital, which is on the principle of the hospitals in Paris, contains one hundred beds, *constantly* occupied by instructive cases.

A large ward has been opened for the reception of children, on the plan of the "*Enfans Malades*," and will afford opportunities for studying the diseases of early life.

Connected with the hospital is an extensive Dispensary, where abundant means are presented for the acquisition of medical and surgical knowledge.

The hospital will be visited daily at eight o'clock a.m.

Clinical Lectures will be delivered twice every week during the session, and Clinical Instruction daily.

The Clinical Lectures will be illustrated by a splendid collection of Original Drawings, Casts, and Preparations.

Certificates of attendance on the practice of this hospital are recognized by the Colleges of Surgeons in London and Dublin; the London University; the Queen's University in Ireland; the Apothecaries' Halls, Dublin and London; the Army and Navy Medical Boards, &c. &c.

☞ In order to encourage that branch of study, Dr. O'Ferrall will, at the end of the session, award a prize to the pupil who shall produce the series of cases containing the most accurate description of Diseases in Children.

Medical Advisers.

First: J.M.O'Ferrall, Esq., M.D., M.R.I.A., F.R.C.S.
Second: O'B. Bellingham, Esq., M.D., F.R.C.S.

Consultants.

Sir Philip Crampton, Bart., M.D., F.R.S., F.R.C.S.
Sir Henry Marsh, Bart., M.D., M.R.I.A.

Further particulars may be learned by inquiring at the hospital during the hours of attendance.

SCHOOL OF PHYSIC IN IRELAND.

(Established by act of parliament 40 Geo. III. and under the joint Government of the Board of Trinity College and the King and Queen's College of Physicians.)

The Professors will commence their Annual Courses of Lectures and Hospital attendance,

On Monday, the 3rd of November,

At 10 o'clock, Dr. Law, on the Institutes of Medicine and Pathology, every Wednesday, Thursday, Friday, and Saturday.
11 ,, Dr. Osborne, on Materia Medica and Pharmacy, every Wednesday, Thursday, Friday, and Saturday.
11 ,, Dr. Robert W. Smith, on Surgery, every Monday and Tuesday, and at one o'clock every Saturday.
1 ,, Dr. Harrison, on Anatomy and Physiology.
2 ,, Dr. Apjohn on Chemistry.
3 ,, Dr. Banks, on the Practice of Medicine, every Monday, Tuesday, Wednesday, and Thursday.
4 ,, Dr. Montgomery, on Midwifery and the Diseases of Women and Children, every Monday, Tuesday, Wednesday, and Thursday.

The course of Practical Anatomy, and of Anatomical Demonstrations, will be conducted by the Professor of Anatomy, assisted by the Demonstrators, Dr. J. Hill and Dr. Samuel Gibson.

Sir Patrick Dun's Hospital will be visited at twelve o'clock daily by the Clinical Professors, and Clinical Lectures will be delivered twice in each week during the Winter Session, as also during the months of May, June, and July.

The Lectures on Botany, by Dr. Allman; and on Medical Jurisprudence, by Dr. Brady; and the Course of Practical Chemistry by Dr. Apjohn, will be delivered during the Summer Session.

The fee for each course of lectures is two guineas; for each course of clinical lectures, three guineas; for attendance on the practice of Sir P. Dun's Hospital to students in arts of two years' standing, three guineas; to other students, ten guineas.

Richd. Macdonnell, D.D.,
Registrar, T.C.D.
Wm. Edward Steele, M.B.,
Registrar to the King and Queen's College of Physicians in Ireland.

CARMICHAEL SCHOOL,

FORMERLY THE

RICHMOND HOSPITAL SCHOOL OF ANATOMY, MEDICINE, AND SURGERY,

North Great Brunswick-street,
(Near the Linen Hall,)
DUBLIN.

WINTER SESSION OF 1851-52.

The Winter Course of Lectures will commence on Thursday, the 30th of October, at twelve o'clock, and continue Six Months.

Anatomy and Physiology—Dr. Mayne, Dr. McDowel, and Dr. Maconchy.
Theory and Practice of Surgery, and Operative Surgery—Dr. Power and Mr. Hamilton.
Theory and Practice of Medicine—Dr. Corrigan.
Medical Jurisprudence—Dr. O'Reilly.
Midwifery and Diseases of Women and Children—Dr. Denham.
Chemistry—Dr. Davy.
Materia Medica and Therapeutics—Mr. Macnamara.
Botany and Natural History—Dr. Frazer.
Demonstrations—Dr. Maconchy, Dr. Cryan, and Dr. Byrne.

An extensive Museum of Materia Medica has been lately furnished.

A spacious and thoroughly ventilated Dissecting-room has been recently erected.

Dr. Maconchy and the Demonstrators, Dr. Cryan and Dr. Byrne, will attend constantly in the rooms to assist the students in practical anatomy.

Certificates of attendance on the Lectures delivered in this school are received by the Queen's University in Ireland, the different Colleges of Surgeons, the Army and Navy Medical Boards, the Universities of Glasgow, London, St. Andrew's, and Aberdeen, the Faculty of Glasgow, and the Apothecaries' Halls, London and Dublin; by the King and Queen's College of Physicians in Ireland, &c.

CARMICHAEL PREMIUMS.

By a bequest of the late Richard Carmichael, Esq., these premiums have been continued in the school. Public Examinations will therefore be held, and premiums awarded, at the termination of the Course, to the best answerers in the various branches taught in the school.

For further particulars apply to Dr. Power, 95, Harcourt-street; Dr. Mayne, 13, Upper Gloucester-street; Mr. Hamilton, 37, Westland-row; Dr. McDowel, 10, Great Denmark-street; or Dr. Maconchy.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT
AT
G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention;* to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

Bleeding, Cupping, the Application of Leeches, &c.

G. O. and Co. continue to be supplied with the Foreign Mineral Waters Fresh from their various Springs.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

MEDICAL SCHOOL.

ANDERSON'S UNIVERSITY, GLASGOW.

The Winter Session will begin on Tuesday, November 4, 1851. Lectures will be delivered daily for six months on the following branches of medical science:—

Anatomy, Descriptive and Physiological—Dr. M. S. Buchanan.
Anatomy, Demonstrative and Surgical—Dr. M. S. Buchanan.
(Demonstrator—Dr. George Buchanan.)
Principles and Practice of Surgery—Dr. Hunter.
Principles and Practice of Medicine—Dr. A. Anderson.
Institutes of Medicine—Dr. Eben. Watson.
Materia Medica, Pharmacy, and Dietetics—Dr. Easton.
Chemistry—Dr. Penny.
Practical Chemistry—Dr. Penny.
Midwifery and Diseases of Women and Children—Dr. Paterson.
Medical Jurisprudence and Police—Dr. Crawford.
Natural Philosophy (three times a week)—Dr. Taylor.
Mathematics—Mr. Laing.

Summer Courses of Anatomy, Midwifery, Chemistry, Materia Medica, and Botany, begin in May.

Botany—Mr. Bell.

Fee for each Class, £2 2*s*.

Classes for French, Drawing, and German are also taught in the University.

Certificates of attendance on the above courses are received by the Universities of Oxford, Cambridge, London, Aberdeen, and St. Andrew's; by all the Royal Colleges of Surgeons in Great Britain and Ireland; by the Faculty of Physicians and Surgeons in Glasgow; and by the Army, Navy, and East India Boards; and the Apothecaries' Company.

Students attending the Medical Classes have the opportunity of witnessing the practice of the following hospitals:—viz., Lying-in Hospital, 10*s*. 6*d*. for six months; Eye Infirmary, £2 2*s*. for six months; Royal Infirmary, £8 8*s*. for two years, including Medical and Surgical Clinical Lectures, which are delivered four times weekly. The patients admitted to the Eye Infirmary average 900 annually; those admitted to the Royal Infirmary, nearly 3000; besides 6000 out-patients, treated at the Dispensary. Average number of surgical operations 120 annually.

The Dissecting-room is free to those attending either of the above Courses of Anatomy, and attached to it there have been opened a Reading-room and Museum for the use of the Anatomical Students.

The new and extensive Laboratory of the Institution, fitted up expressly for gentlemen desirous of pursuing Practical and Analytical Chemistry, is open daily from eleven till four o'clock. No charge for apparatus and materials in the class for Practical Medical Chemistry.

The University Museum, a splendid collection of specimens of Natural History, including more particularly those of Zoology, Mineralogy, and Antiquities, is open to all students attending the University.

A valuable Medical Library is also attached to the Medical School.

TO THE MEDICAL PROFESSION.

JOHN GEORGE BOILEAU AND CO.,

In calling the attention of their Medical Friends to the Quality of their Drugs, which they guarantee as perfectly genuine, would also inform them that, in connexion with their business, they have attached a large and voluminous branch—namely, "Druggists' Sundries and Medical Appliances," consisting of Glass Bottles of every size, Glass Measures, Trusses, Pill Boxes, Scales and Weights, &c., &c., and for these articles we solicit your orders. We are always supplied not only with the British Chemicals, but with the German and French of finest description, and shall esteem any orders you may kindly favour us with.

Wholesale Druggists and Manufacturing Chemists,
Importers of German Leeches,
26, MARY'S-ABBEY, DUBLIN.

Sole Wholesale Agents for White's Saccharized Hydrate of Magnesia.

In bottles, 1*s*. *each*.

THE ROYAL MEDICAL HALL,
64, DAME-STREET, DUBLIN.

☞ *Change of Proprietorship.*

BEWLEY, OWEN, AND CO., APOTHECARIES,

(LATE BEWLEY, FISHER, AND CO.)

In announcing the entire change which has taken place in the proprietorship and management of

THE ROYAL MEDICAL HALL,

beg particularly to state, that henceforth

THE PREPARATION OF MEDICINES AND THE COMPOUNDING OF PHYSICIANS' AND SURGEONS' PRESCRIPTIONS,

will constitute a *legitimate* and prominent department of the Business of their Establishment, and that special attention will be devoted to its cultivation. No pains will be spared in order to obtain the implicit confidence of the medical profession and the public, as well in regard of promptitude and carefulness in the execution of orders, as in the genuineness and quality of the medicines employed.

Besides the Compounding of Prescriptions, as referred to above,

BEWLEY, OWEN, AND CO.'S ESTABLISHMENT

embraces the SALE OF EVERY ARTICLE properly connected with the business of Pharmaceutical Chemists and Apothecaries, and of use in the sick-room and nursery.

*** GENUINE COD-LIVER OIL,

of the finest description.

The Proprietors beg to direct attention to their extensive stock of Chemicals and Chemical Apparatus, among which are some articles not frequently attainable.

THE MIDLAND RETREAT,

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY,)

For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System,

Under the direction of Dr. JACOB,

Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

PROFESSOR PORTER'S SURGICAL WORKS.

OBSERVATIONS ON THE SURGICAL PATHOLOGY OF THE LARYNX AND TRACHEA.

Chiefly with a view to Illustrate the Affections of those Organs which may require the operation of Bronchotomy.

OBSERVATIONS ON THE SURGICAL PATHOLOGY AND TREATMENT OF ANEURISM.

By WILLIAM HENRY PORTER, M.D,
Surgeon to the Meath Hospital and County Dublin Infirmary, Consulting-Surgeon to the City of Dublin Hospital, and Professor of the Theory and Practice of Surgery in the Royal College of Surgeons in Ireland, &c. &c.

Dublin: Fannin and Co., Grafton-street.

Mr. Porter is preparing for publication his Lectures on VENEREAL DISEASES, with additional Notes and Illustrations.

Just published, 8vo, pp. 96, price 2s. 6d.,

A TREATISE ON CATARACT;

Including the Structure of the Crystalline Lens, the Nature of its Opacities, and the Operation for its Removal by Absorption, with the Fine Needle through the Cornea.

By ARTHUR JACOB, M.D., F.R.C.S.,
Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.

Also, lately, by the same Author, 12mo, price 5s.,

THE INFLAMMATIONS OF THE EYEBALL:

Being a Treatise on all the Species and Varieties of Iritis.

Dublin: Fannin and Co., 41, Grafton-street, or the Office of the MEDICAL PRESS, 15, Molesworth-street. London: John Churchill, Princes-street, Soho.

Just published, 8vo, price 7s. 6d., cloth,

PATHOLOGICAL AND PRACTICAL OBSERVATIONS ON STRICTURES, AND SOME OTHER DISEASES OF THE URINARY ORGANS.

By FRANCIS RYND, Esq., A.M., M.R.I.A.,
Fellow and Member of Council of the Royal College of Surgeons in Ireland; Surgeon to the Meath Hospital and County of Dublin Infirmary; Her Majesty's Medical Superintendent of Convicts in Ireland; Member of the Royal Medical Society of Edinburgh, of the Pathological Society of Edinburgh, of the Pathological Society, &c. &c.

"In this treatise the causes, nature, and symptoms of stricture are explained; and its consequences, including disease of the bladder, retention of urine, and abscesses in the perinæum, described. The treatment, both local and constitutional, is laid down; and the management of the catheter and bougie fully detailed. Disease of the prostate gland is also investigated, and its treatment considered. It contains in brief space, and at a moderate price, much valuable and instructive matter touching a subject which no surgeon can overlook. To us it appears a useful addition to our stock of information on this subject, and creditable to Irish surgery."—*Medical Press.*

"No volume was ever more correctly named according to its contents than that which is now before us, the diseases of which it treats are described from nature, the views which it propounds are based on pathological science, and the treatment recommended is derived from an extensive practical acquaintance with the almost endless forms under which diseases of the urinary organs present themselves to the surgeon. We know of no work that presents such comprehensive or such admirable rules on the subject of treatment."—*London Medical Gazette.*

"The book is very carefully written, and may be consulted with advantage by those who are desirous of refreshing their knowledge, as also by the student."—*London Journal of Medicine.*

"The subject of fistula in perineo and its complications are treated of in this book in a remarkably clear and judicious manner. The remarks, &c., may be read with profit by all reflecting surgeons. It is, without doubt, an able and thoughtful production, and has our cordial recommendation as one of the best of the modern contributions to this branch of surgery."—*British and Foreign Medico-Chirurgical Review.*

"There is much that is good, both as regards the matter contained, and the manner in which the work is written. The remarks upon forcibly penetrating an impermeable stricture in retention, are excellent. There is much sound and valuable matter in this book."—*Lancet.*

"The practical precepts with which it is replete will amply remunerate the reader for the time expended in its study. We again repeat it as our deliberate opinion, that these 'Pathological and Practical Observations on Stricture' reflect great credit upon the Author."—*Dublin Quarterly Journal.*

"We have been much pleased with the perusal of this work: it is full of sound practical research, and contains much that will prove valuable to the surgeon."—*Medical Times.*

"It is eminently practical, which is the highest praise that, in my opinion, can be given to a surgical essay."—*Sir Philip Crampton's Letter to the Author.*

"Your book is an important addition to the series of Meath Hospital Works."—*Dr. Stokes's Letter to the Author.*

Longman, Brown, Green, and Longmans.

Lately published, 12mo, price 4s.,

OBSERVATIONS ON ANEURISM AND ITS TREATMENT BY COMPRESSION.

By O'B. BELLINGHAM, F.R.C.S.I.,
One of the Surgeons of St. Vincent's Hospital.

"In our opinion, he has conferred a signal benefit upon the art of surgery by his improvement of the mode of employing pressure, and upon the science by his ingenious and philosophic exposition of its operation."—*Medico-Chir. Rev.*

"Dr. Bellingham has ably advocated the cause of compression as a highly useful and successful mode of treating numerous cases of external aneurism."—*Lancet.*

"Dr. Bellingham's little work is well worthy of attentive perusal, and we feel a confident hope that henceforth another formidable operation (as ligature of the femoral vessel even under favourable circumstances unquestionably is) may in a great majority of instances be avoided."—*American Journal of the Medical Sciences.*

"The very excellent and practical essay lately published by Dr. Bellingham, to which we would refer our readers, as containing a most masterly account of the treatment of aneurism by compression."—*British and Foreign Medical Review.*

"I conceive that for a just exposition of the principles on which that mode of treatment should be conducted, as well as for some valuable improvements in the mode of procedure itself, the surgical profession is mainly indebted to you."—*Sir Philip Crampton's Letter to the Author.*

London: John Churchill, Princes-street, Soho.
Dublin: Fannin and Co., Grafton-street.

Lately published in one vol. 8vo,

LECTURES AND OBSERVATIONS ON CLINICAL SURGERY.

By ANDREW ELLIS, F.R.C.S.I.,
Professor of Surgery in the School of Medicine, Cecilia-street, and Surgeon to Jervis-street Hospital, &c. &c.

Opinions of the Press.

"Many of the diseases treated of are precisely such as the practitioner, in remote districts is frequently called upon to treat under circumstances when the entire responsibility must rest upon himself; he will find in this volume a safe and practical guide under many difficulties and embarrassments."—*Dublin Medical Press.*

"We consider the volume before us one of a truly practical character, and tending to impress upon the mind of the student the vast importance of studying surgery at the bedside of the patient; it contains much of what will be found truly valuable in practice, and suitable both for the practitioner and student."—*Dublin Journal of Medical Science.*

"Its details bear the stamp of actual observation, and are arranged with that plain and straightforward clearness which satisfies us that the author is a sensible and practical man. . . . . We have read it with much interest, and strongly recommend it to the profession."—*London Medical Gazette.*

"The plan and execution of this work are exceedingly good. Mr. Ellis seems to have been well supplied with important cases, and has spared no pains to make his discourses both interesting and instructive. . . . . In conclusion, we would again recommend this book to the profession as a useful and instructive work: the chapters on injuries of the head, and wounds of the abdomen, will be found particularly interesting to the practical surgeon."—*Edinburgh Monthly Journal.*

"The student and young surgeon will find much useful information and many sound practical directions conveyed under the several heads, and even the experienced practitioner will read with interest some of the lectures."—*Provincial Medical and Surgical Journal.*

Dublin: J. Fannin and Co. London: Longman and Co.: Edinburgh: Maclachlan, Stewart, and Co.

In press, and will be published in November,

THE DESCRIPTIVE AND SURGICAL ANATOMY OF THE ARTERIES, AND RELATIVE ANATOMY OF THE VEINS AND NERVES.

By J. H. CORBETT, M.D.,
Professor of Anatomy and Physiology to the Apothecaries' Hall of Ireland, and Lecturer in the School of Medicine, Cecilia-street, Dublin.

MR. CHURCHILL

IS HAPPY TO ANNOUNCE THE COMPLETION OF

MACLISE'S SURGICAL ANATOMY.

The testimony of commendation from the whole Medical Press has created a sale which has nearly exhausted the edition of 1000 copies.

It is the cheapest Illustrated Work ever produced in this country.

TO MEDICAL STUDENTS.

FANNIN AND CO.,

MEDICAL BOOKSELLERS AND SURGICAL-INSTRUMENT MAKERS,

41, *Grafton-street,*

Opposite Chatham-street,

Beg leave to suggest to Medical Students that they will find it their advantage to purchase at their Establishment.

They engage to deal with them on the most liberal terms in any purchases they may make, and claim their support only on the ground of giving

Good Articles at the Cheapest Rate.

On this ground, therefore, they solicit an inspection of their stock, which they have laid in on the most advantageous terms, of the best description, and which, to meet the exigencies of the times, they are prepared to sell on

The lowest possible terms for Cash.

They have made a great reduction in the prices of the Medical Class-books and Manuals, and all the Medical and Surgical Works used by Students.

They have paid particular attention to the supply of those instruments required by the

Dissecting and Hospital Classes.

They have *Dissecting Cases* at
6*s.* 6*d.*, 7*s.* 6*d.*, 10*s.* 6*d.*, 12*s.* 6*d.*, 14*s.*, 15*s.* 6*d.*, 17*s.* 6*d.*, 18*s.* 6*d.*, 25*s.*, *&c., up to Two Guineas.*

Pocket Cases for Hospital Practice, at
10*s.* 6*d.*, 15*s.*, 18*s.* 6*d.*, 24*s.*, 26*s.*, 31*s.* 6*d.*, 35*s.*, 40*s.*, 42*s.*, *up to Six Guineas.*

Their Medical Reading-room,

which is open till eleven o'clock at night, is furnished with a good Medical Library. The subscription is only one pound for the whole session.

The subscription to their

Medical Circulating Library,

from which Books will be lent out on depositing their value, is only £1 6*s.* for the whole session; 16*s.* 6*d.* quarterly, &c.

*** *The accommodation of their Establishment is at all times at the service of the Medical Profession, for writing letters, consulting Medical Periodicals, or holding appointments with professional friends, for which last purpose a private room can be had, if required.*

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin.

LECTURES.

EXTRACTS FROM LECTURES DELIVERED AT VARIOUS TIMES IN STEEVENS' HOSPITAL.

By Sir Henry Marsh, Bart.

(Reported by Henry Freke, A.B., M.B.)

(Continued from Vol. XXV., p. 35.)

We meet occasionally, gentlemen, with cases of simple or non-tubercular abscess from which no fœtid or offensive odour emanates. Such cases, compared in frequency of occurrence with other pulmonary diseases, and with pneumonia as it ordinarily occurs in practice, are rare. They are also far less frequent than pneumonia ending in fœtid abscess. They, however, run the same course, and present the same phenomena as those which are characterized by a highly fœtid odour. Pneumonia without abscess is amongst the diseases which, affecting the pulmonary tissue, we, in the course of daily experience, both in and out of hospital, perpetually meet with. Pneumonia grows as it were out of bronchitis. It is coexistent very frequently with pleuritis. It is kindled up during the progress of pertussis, and augments its danger. In rubeolous and other exanthematous fevers, its ingress throws a gloom over the whole ultimate prospect of the case. In typhus and maculated fever it sometimes stealthily establishes itself, and, like a thief in the night, often robs the patient of the little remaining chance of recovery.

More than once we have had epidemics of typhoid pneumonia. It is remarkable how very few of all these cases of pneumonia terminate in abscess. The tendency of the disease when typhoid is to terminate in a diffused exudation of purulent matter rather than in an abscess. Very frequently in such cases the pneumonia is double: in obedience with the law of symmetry, both lungs are simultaneously affected. Generally, too, in such cases, the inflammation is diffuse or erysipelatous, and therefore much more likely to end, not in circumscribed abscess, but in a purulent infiltration. When the pneumonia is single, circumscribed, and in a great measure uncomplicated, it is apt (if not nipped in the bud by prompt treatment) to issue in abscess. When conjoined with and growing out of other serious affections, particularly adynamic fevers, when it affects both lungs, it is then diffuse in its character, and such, too, is the purulent exudation. I have spoken of a latent pneumonia in adynamic fever. Be careful never to confound mere gravitation of fluids and consequent consolidation with true pneumonia. When the respiration is feeble and scarcely audible—when muscular power is in utter abeyance—when the impulses of the heart and arteries are barely perceptible—when the patient is unable to change position, and lies totally supine—when, at the advanced stage of fever, the blood is wholly altered in quality, then the fluids will gravitate even as they do after death. The air-cells posteriorly will be choked up, no air admitted, and a deceptive semblance of pneumonia will be generated. I have known this all but cadaveric state to be mistaken for true pneumonia, and antiphlogistic treatment substituted for that which is sustaining and stimulating. I deviate from my track to give you this warning. Even after death accuracy of observation is required to distinguish between the extravasation and congestion caused by gravitating fluids and the same phenomena produced by inflammatory action.

The signs of pneumonia, local and constitutional, are, during the progress of adynamic fevers, so masked, that without the utmost vigilance, its early symptoms may escape detection. The difficulty of an accurate diagnosis is sometimes much increased by the extreme prostration of strength and feebleness of muscular power to which the patient is reduced. The patient is incapacitated from maintaining the erect position for a length of time sufficient to admit of an accurate examination of the lungs posteriorly; even the change from one side to the other (particularly if the patient be corpulent) is often difficult of attainment. In these circumstances you will find much advantage in using the curved stethoscope invented by Dr. John Jacob, Surgeon to the Queen's County Infirmary. One of these, exceedingly well constructed, and finished in the nicest manner, he some time since very kindly presented to me. It is metallic, and conducts sound as truly

any stethoscope I have ever applied to the ear. A curved joint is screwed on at the lower extremity, at that farthest from the ear-piece; by this the stethoscope is lengthened, and its form curved. The patient's chest may be examined posteriorly, requiring only the slightest lateral change of position. The curved joint may be screwed off. It is easily carried; it being removed, and the bulb screwed on, you have a straight stethoscope for ordinary purposes. The bulb, which may be screwed either to the straight or curved form of stethoscope, is made of ivory, as is the ear-piece, which also may be screwed on and off. I have repeatedly tested Dr. John Jacob's newly-invented stethoscope. It has answered fully my expectation. It enables the auscultator to estimate the respiratory sounds without subjecting the patient to any difficult or distressing change of position. It may be well to mention that Dr. Jacob's stethoscope is furnished with the gum-elastic ring invented by me many years ago. The first ear-piece of this kind which has ever been made was constructed upon my plan by Dr. Philip Crampton, then clinical clerk at Steevens' Hospital. The ear-piece was turned and grooved by Mr. Betham with his own lathe. It was excellently well done. The first percussor attached to the ear-piece which I ever possessed was constructed, under my direction, by these gentlemen. By it percussion can be practised with the greatest accuracy. In general the elastic ring is too small. The vulcanized Indian rubber is less elastic than the pure caoutchouc, and therefore I think less suited to the purpose. The greatest difficulty I had to encounter was so to attach the Indian rubber ring to the groove, that not any, even the slightest jingling sound, should be produced. I tried a variety of intervening glutinous substances; they soon lost their adhesive property; at length it occurred to me that, by putting the ring into its place at a temperature not below 98 or 100, it would, when cooling, contract and adhere firmly and spontaneously. This was carried into effect under the superintendence of my friend Dr. Hill: it has been completely successful. The ear-piece which I employ is of ivory, the upper surface being concave to fit the ear, the under surface perfectly flat: its diameter is two inches and a half: its thickness at the margin half an inch, and thickness at the centre five-twelfths of an inch. The margin of the ear-piece is grooved, to receive a thick Indian rubber ring or bolster, which projects four-twelfths of an inch beyond the margin. The value of this percussor is proved by its having been so generally adopted. Its dextrous and successful application requires practice.

I have said, gentlemen, that we occasionally (by no means frequently) meet with a case of simple pulmonary abscess without fœtor.

The following is an unusual example of it:—The patient was an infant only eleven months old, a fine and well-nourished child nursed by its mother. Its brothers, sisters, and parents were exempted from any strumous taint or imperfection. For several days before my first visit, the child suffered from almost incessant cough, with fever, restlessness, and urgent dyspnœa. The symptom so well known to nurses, and by them termed "a draw," existed in a remarkable degree. At each inspiration, accomplished with great muscular effort, a deep pit or depression is created between the thyroid muscles, and also at the epigastrium; this, in infants, is one of the surest signs of the existence and degree of dyspnœa. The child was so unquiet that I could not for some time effect a satisfactory examination. Taking advantage of a moment of exhaustion and sleep, I was enabled to attain the object. The contrast between the sides of the thorax was remarkable; most so, at the inferior angles of the scapulæ. On the left side, this region when percussed was perfectly dull, and a breath-sound scarcely audible; whereas, on the right side, these sounds were loud and sonorous; few and slight were the bronchial râles. In all other regions the percussion-sounds were tympanitic, and the breath-sounds puerile. The early history of the disease would have led one to suppose that an extended bronchitis had been the starting point of morbid action. Fever, distressing cough, and sleeplessness had reduced the child to an extreme degree of prostration, which, with the urgent dyspnœa, deprived it of the power of suction. It was nourished by its mother's milk from a spoon. Several days were in this manner passed in a desperate struggle between life and death, when, at length, in the act of vomiting, a mass of purulent matter (at least two tablespoonfuls) was ejected. It was scarcely intermingled with any foreign matter; there were few air-bubbles, and it was inodorous. It was reserved for my inspection as a curiosity. Great relief and abatement of every urgent symptom ensued. For several successive days purulent matter in lesser quantities was ejected. The symptoms gradually subsided, and in no long time health was reëstablished. The duration of the disease, from the commencement to convalescence, involved a period of eight weeks. Months afterwards I examined this child's chest, and could perceive no difference between the affected and unaffected side of the thorax. This is the only instance of pulmonary abscess in an infant that I have it in my power to record. Perhaps if the chests of infants were more minutely examined (not always an easy task) the result might be different.

During the time of my attendance upon this infant I saw several times, in consultation with Dr. Churchill, a very interesting case of inodorous pulmonary abscess. The lady before her confinement was affected with acute bronchitis of great extent and severity. In no instance have I witnessed greater rapidity of pulse and breathing, nor a more harassing and unintermitting cough, and these in a constitution innately nervous, restless, and in the extreme excitable. While in this perilous state she was seized with labour pains, and was safely delivered.

This lady was treated and managed with great skill by Dr. Churchill. Soon after parturition, the symptoms of bronchitis rather suddenly passed away; still all was not right. Fever, cough, dyspnœa, though in degree much mitigated, persisted. At this period the examination of the chest made known the cause. The local signs of pneumonia, and subsequently of abscess located at the base of the left lung, were unequivocally evinced. I shall not trouble you with the minutiæ of this case; so to do were to traverse ground already trodden. Suffice it to say, that in no instance were the paroxysmal nature of the cough and the completeness of the remissions more distinctly and strikingly observable. After the first severe cough with profuse purulent expectoration, so perfect was the relief, so total the subsidence of pulmonary distress, that no words I could employ availed in convincing the patient or her friends that the disease still persisted. After the lapse of about forty hours, a similar paroxysm, with an equally abundant expectoration, dispelled the illusion. At varying intervals, and with varied degrees of severity, these paroxysms recurred; nor did they wholly cease till after her removal to pure country air. It may

be worthy of remark, that the exacerbations and remissions which characterized this case were not manifested till the first and second stages of pneumonia had passed away; not till an abscess was formed and the bronchial communication fully established. It strikes me that the communication must, to give rise to this phenomenon, be a free and open one. The pent-up matter must escape with facility, so that, during a single coughing paroxysm, the abscess may be very much evacuated. Paroxysmal catarrh characterizes many thoracic affections. It is always an important symptom; peculiarly so when the result of the catarrhal paroxysm is a muco-purulent expectoration, with or without the admixture of blood. In some cases of tubercular abscess I have noticed these remissions; rarely, however, so perfect as in some cases of non-tubercular abscess.

The more perfect the remission, the longer the interval of time between the paroxysms, the better, I would say, as a general rule, is the omen. There is a something in the sound of the cough, as well as in the manner of coughing, which distinguishes the efforts to force up matter from a cavity with open tubes from the cough which results from every other pathological condition of the lungs, air-passages, and membranes. The sound of the cough is peculiar; the manner of coughing is peculiar. This is notable in large tubercular abscesses; even the uninitiated recognize the sound. Often have I heard it said, such an one has a hollow, and but too truly, a churchyard cough. A non-tubercular abscess is frequently formed at or near the base of the lung; and when so situated the labour of expectoration is much increased, and often far greater than in a tubercular abscess located near the apex.

(To be continued.)

ORIGINAL COMMUNICATIONS.

CASES OF PULMONARY DISEASE.

By Edmund Sharkey, A.B., M.B., T.C.D., Ballinasloe.

The following cases are scattered over a practice of about twenty years, and having been treated in different localities may, perhaps, appear interesting on that account:—

Case 1.—*Incipient Phthisis—Treatment by Frictions of Ointment of the Iodide of Potassium—Recovery.*

Dublin, 28th of November, 1830. An interesting little girl, ætat. 11, presenting the scrofulous complexion and features, had scarlatina, accompanied by pectoral symptoms, some years ago; this was followed by intermittent fever. Since that time her chest has continued delicate; she has had a cough for three years, aggravated within the last few weeks, and accompanied by loss of appetite, depression, and emaciation to a certain extent. Her present symptoms are cough, so severe as to prevent sleep; expectoration copious, principally at night; pulse 120; tongue clean; bowels regular. *She has distinct rigors towards evening.*

Physical signs.—Percussion clear over every part of the chest except the right supra-scapular region, where a shade of dulness coexists with feeble respiration; slight vocal resonance and distinct sound of heart's action, and a little mucous râle, heard occasionally, accompanying inspiration, in this situation; respiration is puerile over left scapula.

Considering the foregoing symptoms as presumptive of a tubercular deposit, of greater or less extent, at the top of the right lung, I determined to try the effect of hydriodate of potass—a remedy just then brought into general use. In order to fulfil the several indications—viz., allaying pulmonic irritation, promoting the absorption of the tubercles causing it, correcting the tendency to their deposition, and supporting the strength, I ordered flannel to be worn next to the skin, light nutriment, exercise in the open air proportioned to her strength, and with due regard to the state of the weather. Mucilaginous mixture with camphorated tincture of opium, frictions of unguent. hydriod. potass, twice a day, over the right scapula, and half a wineglass of lime water in milk three times a day. The report of the 11th of December is:—Considerable general improvement; diminution of cough; countenance more lively; appetite better; rigors less frequent; pulse 76. On the 21st, improvement continues; rigors altogether gone; pulse 76.

February 12, 1831. She has continued to improve since last report, notwithstanding the weather was very severe. On examination by percussion and the stethoscope, it appears that the dulness over the right scapula, and resonance of voice in the same situation, have disappeared; and there is no perceptible difference in the strength of respiration as compared on both sides in this situation. No râle audible.

November 25, 1831. I have seen this patient a day or two since, she has continued to improve, and has acquired quite a healthy appearance. It is important to add, that the sister of this girl had been examined by Dr. Stokes, who pronounced her to have a cavity under the right clavicle, and she died with all the symptoms of rapid phthisis.

Case 2.—About this time I also tried the same treatment in the case of a boy who, besides having been long affected with scrofulous complaints of various kinds, presented all the phenomena of a large cavity at the top of the left lung, with great hypertrophy of the heart, and with considerable (though I fear but temporary) benefit; but in the latter case chlorine inhalation was used in conjunction.

Case 3.—Dublin. In the winter of 1842, I was consulted by a young woman of clear, bright complexion and spare form, who complained of short cough, emaciation to some slight extent, and flying pains in the chest. Percussion detected a slight shade of dulness under one clavicle. I gave her pills of hydriodate of potass, gum ammoniac, soap, and oil of juniper. She improved rapidly under this treatment, and when I left was quite well.

Case 4.—Jersey, Sept. 1843. A young unmarried female presented herself to me complaining of the same train of symptoms, and exhibiting similar physical signs. She likewise recovered under the use of the same pills, and, in addition, frictions of iodine ointment under the axillæ, having been directed to inhale the vapour of the iodine contained in the ointment, by keeping her head under the bedclothes for some minutes at a time, and repeating this process. For this simple mode of combining the endemic exhibition of iodine with its inhalation, I am indebted to my friend Dr. Leigh of St. Helier's, Jersey, who has practised it in several instances with the most marked success.

Case 5.—*Incipient Phthisis—Internal use of the Hydriodate of Potass with Decoct. Uvæ Ursi—Recovery.*

Berehaven, county Cork, May, 1841. A boy aged 14, was attacked some weeks ago by a severe pulmonary affection, considered at the time to be pneumonia, and treated with calomel and tartar emetic, by which he was cured. Symptoms, however, succeeded which strongly indicated incipient phthisis—viz., cough, dyspnœa, accompanied by hectic paroxysms. And he also presented the following physical signs:—Lungs generally clear, except over the superior angle of the left scapula, where well-marked bronchophony accompanies the dulness. I ordered him a mixture containing hydriod. potass 3ij, to one pound of mucilaginous mixture, of which he was to take a wineglassful three times a day. Tartar emetic ointment was rubbed over the left scapula, and he was ordered to drink a decoction of uvæ ursi as his common drink. On the 9th of June the report is that he is much improved, the cough diminished, and he is gaining flesh and strength. In December he had quite recovered.

Case 6.—*Incipient Phthisis.* Ballinasloe, April 16, 1850. A young lady, aged 20, with light hair, fair skin, delicate complexion, and great sensitiveness, of a scrofulous family, and whose elder sister died of well-marked

phthisis, has been for some time affected with short cough, flying pains in the chest, and evident bronchitis of the upper part of the right lung, manifest to her own sense of hearing by a wheezing, which she describes as a constant "tick," accompanying inspiration and expiration, and which is only removed by expectoration of mucus. She has enjoyed until lately a good state of health; has had a good appetite, took constant exercise in the open air, and was possessed of an exuberant flow of spirits, often betraying her into acts of imprudence, such as exercise beyond her strength, exposure to damp and night air, singing to the extent of producing pain of her chest, &c. Since the present affection commenced, she has suffered frequently from very deranged stomach, evidenced by a very morbid condition of tongue, loss of appetite, and depression of spirits. There is now a mucous râle heard in the right subclavicular region, with feeble respiration, and a slight but very decided dulness on percussion. I recommended frictions with iodine ointment under the axillæ, and directed her to inhale its vapour, as elsewhere mentioned, and the following pills—viz.,

℞ Gum. ammoniac 5j,
Potass. hydriod. 3ss,
Olei juniperi gtt. xvj,
Saponis q. s., ft. Massa in pil. xxxvi.
Dividenda quarum sumatur i. ter in die.

Diet to consist principally of milk, but not to the exclusion of tender meat; no wine nor other stimulant drink. She was also sent to the sea-side.

January 10, 1851. She returned, very much improved, in the autumn, and has since gained flesh and strength, and quite lost her cough. I should add that she used cod-liver oil also.

These are a few of the cases treated on this plan, in which the good effects seemed striking. In others, of course it was less beneficial, or altogether failed, as, I need scarcely say, has every other mode pursued in this disease.

I bring them forward, not for the purpose of proclaiming a panacea, but merely to show that there is a chance of rescuing an occasional victim by the judicious selection of a particular line of treatment suited to the case in hand. There are other cases of incipient phthisis to which this line of practice is not adapted—cases calling for a modification of the antiphlogistic treatment suited to the character of the disease, and to which I shall hereafter direct attention. I know it may be said that, after all, these might not have been cases of phthisis at all; that they might have been instances of mere localized pulmonary irritation, or circumscribed congestion at the heart; but I would ask what more are we to expect to be substantiated in any incipient case—in that stage which alone we are warranted in considering curable? Dr. Stokes and other high authorities are of opinion that the tubercular deposit in every case is preceded by a degree of solid deposit, which, *when situated near the thoracic parietes*, will yield dull sound on percussion. It is impossible to distinguish by the ear, or by any other known means of diagnosis, whether a shade of dulness accompanying such a train of suspicious symptoms as those above detailed, is a congestion of the ordinary kind, or the specific one preceding the deposit of tubercle. There is, however, a strong presumption of the latter where it is found occurring in a scrofulous subject, as in a member of a phthisical family.

The cases in which the practice here detailed appears to me to be suited are those of the chronic kind, in which there is either an absence of hectic, or also the amount of hectic present is rather a constitutional sympathy accompanying a deranged function, than that arising from inflammation in the pulmonary tissue or minute bronchial tubes, and where there is, therefore, time allowed for a remedy directed specially to stimulation of the absorbent without injurious excitement of the vascular system. These, it will be perceived, present a narrow field enough, but it is well to be able to say

"Est quodam prodire tenus si non datur ultra."

The uvæ ursi I have fancied did some service; and this is not inconsistent with analogy and the known sympathy between the bronchial mucous membrane and the urinary system, of which familiar instances are presented in the utility of liquor potassæ and the carbonate of soda in bronchitis and pertussis, and that of turpentine and tinctures of squill and lytta in the same diseases, with others which the reader's experience will readily suggest.

PROCEEDINGS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON—Oct. 18.

Mr. B. W. Richardson made a communication to the society

ON THE THERAPEUTIC USES OF CREASOTE.

He stated that during the last visitation of Asiatic cholera his attention had been called to a short notice, communicated to the *Lancet* and *Medical Gazette* by Mr. Spinks of Warrington, on the astringent value of creasote in that disease. Mr. Richardson had never used creasote in true Asiatic cholera, because the subject had not come before him until the epidemic was nearly over, but he had since fully tested its value as an astringent, and he must say, that in some cases of diarrhœa, he had never before seen half so good a remedy. The cases in which it is most useful are of three kinds: 1st. Cases of diarrhœa during ordinary epidemics, where the disorder cannot be traced to the presence of foreign matter in the intestines. 2nd. Cases where profuse diarrhœa follows the employment of purgatives, given to remove foreign matters during intestinal disorders. 3rd. Cases in which, after an acute diarrhœa, the patient continues to be troubled with frequent and sudden liquid evacuations, not attended with pain or great constitutional disorder. Illustrative cases were supplied. The advantages of creasote are the following: It often succeeds when all other astringents fail; of this the author is thoroughly convinced from repeated experiments; it is speedy in its action; lastly, it does not leave the bowels constipated, unless carried too far in its administration. Occasionally, during its use, it produces a dry, white, filmy state of tongue, and other symptoms of feverishness. When this occurs, the remedy must not be continued longer; indeed, it is rarely required after such symptoms, the purging being usually arrested before they appear. With children the dose given must be very small, or such good results will not follow; the one eighth, one-sixth, and one-fourth part of a drop, is sufficient for babes from one to two years of age. With adults, the dose, as an astringent, is from one and a half to two minims. A late writer in the *Medical Gazette* (Mr. Kesteven) had also alluded to the value of creasote as an astringent, and had opined that this value depended on the power which creasote was known to have, of coagulating albuminous fluids. To this it may be objected, that the quantities of the creasote employed medicinally are not sufficient to produce such coagulation in the intestines. Mr. Richardson also alluded to other effects of creasote. He denied that, in ordinary doses, it possessed some of the properties described as belonging to it in elementary treatises on therapeutics, such as narcotic, sedative, and diuretic properties. At the same time he assigned to it powerful diaphoretic and antispasmodic qualities, and said, that on the vascular system it rather acted as a stimulant than as a sedative. Its power in stopping vomiting depended upon the dose, which should be small. Given in its full dose, as an astringent, it sometimes *excites* vomiting, in which case hydrocyanic acid is usefully combined with it. To lessen its nauseous qualities, it is best to unite it with syrup of tolu and tincture of cardamoms, and camphor julep or water. It may also be prescribed advantageously with the preparations of ether when they are indicated.

Mr. Dendy suggested that the creasote did good in some cases of diarrhœa from its antiseptic properties. Diarrhœa often depended on acidity, and this was removed by the creasote.

Mr. Richardson knew it to be astringent from its effects. It was, no doubt, also a powerful antiseptic.

Mr. Streeter trusted that it would not go forth with the sanction of the society that the premonitory diarrhœa of Asiatic cholera was identical with the ordinary English cholera. They were different affections, and required different treatment. The practice commenced by himself in the epidemic of 1832, and continued in 1834, of giving superacetate of lead with opium after each action of the bowels, had been attended with the most satisfactory results in warding off the impending collapse in that of 1849. He had strongly recommended this practice in the spring of 1849, when his communication of the statistical results of the cholera cases at St. Giles's in 1832 was read at the Medico-Chirurgical Society, and which facts, to the disgrace of the executive, had not appeared in their Transactions. Let it not, however, be supposed that lead was the remedy for collapse—a state which his subsequent studies of Asiatic cholera led him to regard as arising from the abnormal presence of a prussic acid poison in the blood in the place of the normal cyanic element of the true urinous excretion.

Mr. Richardson explained that he did not allude to cases of Asiatic cholera.

Mr. Harrison said that prussic acid was the only remedy which he had found effective in cholera.

Mr. Richardson, in reply to a question of Dr. Lankester, said, that out of 100 cases in which he had employed creasote, he had combined opium with it in six only.

Dr. Lankester believed that in ninety cases out of one hundred, it was the opium that did good in cholera.

GELATINOUS POLYPUS—NEW POLYPUS FORCEPS.

Mr. Harvey exhibited a gelatinous polypus which he had extracted from the ear by means of a new kind of forceps which he had invented for the purpose. He observed that in these cases it was most desirable that the morbid growth should be extracted entire; for if it was broken or otherwise injured in attempts at its removal, it gave rise to much inconvenience, and required tedious and troublesome after-treatment. The forceps which he had constructed, and which he had been in the habit of using for a long time with satisfactory results, were not dissimilar to those of Assalini, but had a somewhat longer blade, were flattened on either side, and terminated with three rows of teeth. The foreign body was firmly grasped by these teeth, and removed by a rotatory motion, the instrument admitting of that. This Mr. Harvey regarded as of great importance to the operator on the ear. It was also sufficiently small to admit of being used with a bivalve speculum in the auditory canal, the operator being thus afforded an opportunity of investigating the origin of polypi. The instrument was shown to the society.

REMARKS ON THE HYDRO-ELECTRIC-CHAIN OF DR. PULVERMACHER.

By Golding Bird, M.D., F.R.S.

The ingenious modification of Volta's pile, contrived by Dr. Pulvermacher of Vienna, has attracted so much attention, that the following account of the value of the apparatus, as a source of electricity, may perhaps not be uninteresting, at least to those who may not have had time to devote much attention to the study of these subjects.

Everybody is aware that the apparatus contrived by Volta consisted of plates of metals, differing in their respective affinities for oxygen, alternated with pieces of cloth dipped in a saline solution. Thus, in the most common modification of this pile, a plate of copper is placed on the table, on this a plate of zinc, and then a piece of flannel or cloth, dipped in a solution of common salt; on this a second plate of copper, and so on. The theory of the apparatus is so well known, that it is unnecessary to say more than that, under the chemical action of the saline fluid on the zinc, the combined electric fluids existing normally in both the two metals employed, are separated,—the positive electricity being found on the zinc, and the negative on the copper surface. Wollaston's and Cruikshank's troughs are but modifications of the same contrivance,—cells filled with the saline fluid replacing the moistened cloth or flannel. The cumbrous nature of these contrivances, the time required to excite them, the rapidity with which the intensity of the electric current diminishes, as well as the tact and management required to apply the current they evolve, have always presented most serious obstacles to their adoption into medical practice. On this account they have been almost completely replaced by the different machines for furnishing a current of induced electricity. These, it is true, possess many advantages, and become most important appliances in the treatment of disease, as has been repeatedly pointed out by myself and others. Still we have often felt the want of an apparatus by which an uniform and uninterrupted current of voltaic electricity could be at our command at a short notice, and without involving the necessity of any manipulative tact in its application. The hydro-electric chain completely fulfils these desiderata.

The apparatus I have used, was placed in my hands, during last winter, by Dr. Pulvermacher himself. He is a scientific man, and well acquainted with physical science generally, nor is he, I presume, responsible for the manner in which his invention has been extolled, as a sort of universal panacea, by the London agent, in the public advertisements. Each element of this battery consists of a small piece of wood, around which are wound two wires, nearly but not quite in contact, one of these wires consisting of zinc, the other of gilded copper. These represent the plates in Volta's pile; each terminates in a ring, by which it is connected with the wires of the next link or member of the chain, the zinc of one being united with the copper of the next, and so on. When one of these links is immersed in a fluid capable of exciting a chemical action on the zinc, enough is retained by capillary attraction between the folds of wire to disturb the electric equilibrium of the metals, and to throw the negative and postive fluids into a state of current. The exciting fluid recommended by Dr. Pulvermacher is common vinegar, and if one of his chains be immersed in that fluid for a minute, and then lifted out, so that all not retained by capillarity may drain off, it will be at once fit for use.

The electricity excited by this apparatus is necessarily small in quantity, as the amount of electricity evolved must be in a ratio with the intensity of the chemical action exerted on the more oxidizable metal; yet its tension is tolerably high. It is indeed, sufficient, both in quantity and tension, for the development of physiological phenomena. The following experiments will illustrate these properties, a chain of fifty alternations being employed:—

A. A thin piece of platinum wire being attached to the terminal links, they were immersed in water acidulated by sulphuric acid, and very distinct evolution of exceedingly minute bubbles of oxygen and hydrogen were evolved from the two wires. The dilute acid being replaced by a solution of iodide of potassium mixed with starch, iodine was almost immediately set free at the wire where the positive current entered the fluid. The quantity of these electrolytes decomposed was exceedingly small, as the electrolytic power of the evolved current would of course bear relation to the amount of effective chemical action going on in the links of the chain.

B. The platinum wires were then connected with an astatic galvanometer; the wires were immediately deviated under the influence of the current, but the latter was not sufficient to retain the needles at right angles to their normal position. The astatic galvanometer was then replaced by an ordinary one, having a coil of thirty folds of wire, and carrying a magnetic needle, five inches long. The current was barely able to produce a permanent deviation from the magnetic meridian of five degrees. This feeble action on the magnetic needle is explained by the small *quantity* of electricity circulating through the chain.

C. The chain being held in a vertical position by one end, the terminal link was allowed to touch for an instant the lower plate of a condenser, six inches in diameter, in

connexion with a gold-leaf electrometer. On lifting off the upper plate the gold leaves separated to the extent of a couple of inches. When only half of the chain was brought in contact with the electrometer, considerable divergence also occurred. This experiment well illustrates the comparative high tension of the evolved electricity.

D. The first and last link of the chain being placed in cups of water, and a finger of each hand being immersed respectively into the two cups, a smart shock was experienced in each finger. This shock was repeated every time one finger was *raised out* of the fluid and re-dipped. But no shock was felt all the time the finger *remained* immersed, as the electricity passed in a continuous stream through the body from one end of the chain to the other. The physiological phenomenon of "shock" being produced only at the moment the current first entered the body. This is of course the same with all voltaic apparatus which yield an uninterrupted current.

These experiments are sufficient to demonstrate the electro-genic power of Pulvermacher's apparatus, and to point out that the current evolved is small in quantity, but of moderately high tension.

When a continuance of sensible shocks is required, an ingenious apparatus, contrived by the inventor of the chain, may be used. This consists of a small helix of thin wire fixed in a glass tube; one end of this wire passes through a cork in the tube, and ends in a hook; the other end is free, and is barely in contact with a metallic plate (also furnished with a hook), which closes the other opening of the tube. On connecting a chain of fifty elements to each of the hooks of this apparatus, the first and last link being grasped in the hands, a rapid succession of rather violent shocks will pass through the arms. These occur in consequence of the slight motion communicated to the chain by the hands, being sufficient to make the helix vibrate, and thus rapidly approach and recede from the plate at one end of the tube.

It must not be supposed, however, that sensible shocks are required to develop physiological phenomena or therapeutical effects. We are chiefly indebted to the laborious researches of Dr. Marshall Hall for teaching us the vast amount of therapeutical influence developed by a continuous current of voltaic electricity. I cannot, indeed, too strongly impress upon those who have to treat a case of old paralysis (unconnected with spasm) the vast importance of allowing a current of voltaic electricity to traverse the palsied limbs persistently for half an hour or more daily for weeks and months, nor to be disappointed at not witnessing any *immediate* good results. Nutrition of the limb is certainly thus increased, its waste and emaciation prevented, at least to some extent, and the probabilities of cure are much increased. Pulvermacher's chain, when once excited by immersion in vinegar, soon begins to evolve a current of decreasing intensity; but so long as even a small quantity of fluid remains unevaporated between the folds of wire, evidence of the circulation of electricity can be made out by the electrometer. A moment's re-immersion in vinegar will at once restore the energy of the current.

The advantages of this apparatus to the medical man consist in its giving him a means of obtaining a current of electricity, of amply sufficient tension and quantity for all physiological purposes, at a moment's notice. He can, moreover, diminish or increase the tension by making use of a greater or smaller number of links. He can make the current continuous or interrupted, painful or painless, at will,—and he has, moreover, an apparatus so easily managed as to require no especial tact for its application. On the other hand, it must be recollected that the current evolved has no *peculiar* properties, and that it will effect nothing more than that evolved by any other means. It is, indeed, deeply to be regretted that so convenient a source of electricity runs the risk of losing favour in the sight of educated men generally, and of our profession in particular, by being injudiciously puffed in the public prints, by advertisements claiming for it a medical influence it in no wise possesses.—*Lancet.*

POPLITEAL ANEURISM CURED BY PRESSURE UPON THE FEMORAL ARTERY.

By G. M. Humphry, Esq.,
Surgeon to Addenbrooke's Hospital, Cambridge.

William Mitchell, aged 24, from Wisbeach, admitted into Addenbrooke's Hospital, August 1849, in ill-health, with anxious pained expression, sallow complexion, pulse 104.

The ham and lower third of the inside of the right thigh occupied by a firm swelling, giving a circular measurement of eighteen inches and a half; the left limb, in a corresponding situation, giving only thirteen inches and a half. The swelling was most prominent a little above the internal condyle, and at the middle of the ham, uniformly firm, but communicating an indistinct sense of fluctuation. Its outline could not be clearly ascertained in consequence of an œdematous condition of the subcutaneous tissues. The integuments were natural, with the exception of a faint blush in places, and a few white starry spots, like cicatrices, which he said had appeared within the last few days. There was effusion into the knee-joint, raising the patella and still further distorting the limb. The part was exceedingly tender, and he suffered great pain in the swelling, and agonizing pains shooting down the limb; the skin of the leg and foot feeling, to use his expression, as if it were being burnt in a fire. He was restless, incessantly turning about to find a more easy position. The limb below the knee was œdematous, rather cold, and devoid of sensation below the middle of the leg; he could not move the foot or toes. The femoral artery could be traced to the lower third of the thigh, where the swelling began. No pulsation could be felt in the anterior or posterior tibial arteries. No pulsation whatever could be felt in any part of the swelling, nor was his severe pain in the slightest degree relieved, or the size of the swelling diminished by pressure upon the artery at the groin, though it was continued for several minutes, so as to prevent the passage of blood. A distinct bruit was audible over the tumour; and there was also a bruit, synchronous with the first sound of the heart, heard over the commencement of the aorta.

He was a sailor. Seventeen weeks before his admission he had been compelled to leave his ship in consequence of an attack of rheumatic fever, which continued severe for about five weeks. During the whole of that time he suffered a good deal of pain about the right knee, more particularly in the neighbourhood of the inner condyle of the femur. When the pain subsided in other parts it continued unabated in the knee. About this time he first observed the swelling, which began on the inside of the ham; it increased quickly and was attended with distinct beating, which he could see and feel with his fingers. He was clear upon this point, and said that several surgeons had examined the swelling and had perceived the beating within the last few days. It seemed probable, therefore, that the cessation of the pulsation was dependent upon some inflammatory changes in the aneurism or the surrounding parts caused by the journey to Cambridge.

He suffered acute pain all night in spite of fomentations and opium, and on the 2nd was still in great agony. The œdema had rather increased. No bruit or pulsation could be perceived in the swelling. Twelve leeches and fomentation applied, and a grain of morphia given at night. 3rd. Less pain; swelling rather less tense; the bruit had returned; still no pulsation. 4th. A further diminution of pain. The swelling softer and fluctuation more evident. Pulsation could now be distinctly seen and felt; but it was limited to the course of the popliteal artery, not being perceptible in any other part of the swelling. 7th. The pulsation of the whole tumour being to-day quite decided and the bruit audible, there remained no longer any doubt as to the nature of the case; so we determined at once to commence treatment by pressure. The arch tourniquet (Santorini's) was applied a little above the middle of the thigh, and the common tourniquet at the groin; the latter being retained in place by a strap round the pelvis and

another round the upper part of the thigh. Great pains were taken to stop completely the pulsation in the artery, and in the tumour; and it required considerable pressure to do this. However, the tourniquets being used alternately, the object was attained continuously for several hours without much inconvenience to the patient; and after fifteen hours of effective treatment, the pulsation in the tumour had entirely ceased. Constant pressure was kept up for two days longer; afterwards the tourniquets were applied only at intervals. In three or four days, when the swelling had begun to diminish, he was greatly troubled with pains in the feet and toes. This was probably dependent on some change going on in the nerve consequent on the partial remission of pressure upon it as the aneurism decreased in size, for on August 30th the pain had nearly ceased. Still there was no sensation below the middle of the leg, and no power to move the foot and toes.

September 4th. No pulsation or bruit; the size of the tumour decreases slowly; the movements of the knee are much more free.

October 4th. Has for some time moved about the ward on crutches, swinging the right leg. Moves the knee boldly though not quite freely. The size of the swelling diminishes very slowly, the circular measurement being still seventeen inches. It is soft and indistinctly fluctuating. Sensation exists over a greater space than it did, but he cannot move the foot and toes, which remain swollen. The femoral artery may be traced to the lower third of the thigh. There is no pulsation perceptible in the tumour or in the tibial arteries. The œdema of the foot might prevent its being felt in the latter. Returned to his home.

In the course of the following winter he was again in the hospital for several weeks, on account of the paralytic condition of the foot, which continued, although the aneurismal tumour was smaller and soft, and pulsation had entirely ceased. Electricity was used with some benefit, and he again went home. Some months afterwards he was attacked with inflammation of the chest, and died. Mr. Burnam, who attended him at Wisbeach, wrote me word that he had recovered the use of the limb, and that the swelling in the ham had almost disappeared before his death.

In this case the origin of the disease in the popliteal artery was clearly traceable to rheumatism. It is very seldom that such a cause can be assigned for the commencement of aneurisms in the extremities; the disease being usually attributed to an injury, a sprain, or to free movement of the part. Even in the thorax the diseases of the arterial coats that give rise to aneurism, are more generally dependent upon age or intemperance than rheumatism.

The extent to which the characteristic symptoms of aneurism were, on the patient's admission, masked by a tense inflammatory condition of the surrounding tissues deserves particular attention. At one time both pulsation and bruit were entirely absent, and pressure upon the femoral artery failed to produce any alteration in the swelling; indeed the swelling then resembled an abscess more than an aneurism, and it is certainly no wonder that mistakes in diagnosis should, under similar circumstances, have, in more than one case, led to serious mistakes in treatment. As the inflammation and tension diminished, first the bruit and then the pulsation returned.

The cure by pressure upon the artery above the aneurism was effected in a shorter space of time than in any other case of which I have seen an account; all pulsation in the tumour having ceased fifteen hours after the treatment was commenced, and it never returned. A case is related in Dr. Bellingham's Observations on Aneurism, treated at the Royal Military Infirmary, Dublin, in which pulsation ceased after ten hours of compression, maintained by two instruments alternately relaxed (the pressure upon the artery being sufficient to check completely the pulsation in the tumour), and it did not return. In this case, however, it is to be observed, that pressure had previously been applied to the artery in the groin by a weight, and had, it was supposed, caused some deposition of fibrin in the aneurismal sac. Not long ago a case was related at the Medico Chirurgical Society, by Dr. Bellingham, in which the pulsation had ceased twenty-three hours after compression had been commenced. In the greater number of cases of which reports have been published, weeks, and even months, of patient endurance and constant attention have been required to bring about a successful issue. Indeed the great, perhaps the only, valid objection to the treatment of aneurisms by compression of the artery above the tumour, is founded on the tediousness of the process, and the pain to which the patient is subjected by the long-continued pressure of the tourniquet. In all other respects there can, I think, be no question that preference is due to the treatment by compression in comparison with that by ligature. Its general efficacy has now been proved in a sufficient number of cases. Of thirty-six cases treated in this way, in Dublin, we are informed that twenty-nine have been cured. If properly conducted, the procedure is almost entirely devoid of danger, either to the limb or to the patient; and, if it fails to effect a cure, the patient has not been placed in a more unfavourable position for the treatment by ligature. In cases where it has been necessary to operate under such circumstances, or where an opportunity has been afforded of dissecting the parts after compression, it has been found, with one or two exceptions, that neither the artery nor its investing cellular tissue, have been subjected to any material alteration at the part pressed upon, so as to increase the difficulty of the operation, or to modify its results.*

From the history of cases, and the dissections that have been made, it appears almost certain that the cure of aneurism, whether the means used be compression or ligature, takes place in much the same manner—viz., by the formation of coagulum in the cavity, and the subsequent absorption of that coagulum and contraction of the sac. The formation of the coagulum appears, in most instances, to be the primary and essential part of the process, and the treatment is likely to be effectual and speedy, in proportion to the degree in which it favours the coagulation of the blood in the sac, by placing it at rest. It is by no means necessary that the artery should be obliterated at any part of its course. True, it commonly is obliterated in the vicinity of the aneurism; but in all the instances of dissection after cure by compression that I have met with, the artery has remained pervious above the aneurism; and even where ligature has been employed, it has not unfrequently remained pervious between the ligature and the aneurism. It is not even necessary that the circulation through the artery should be completely arrested, a mere retardation of the current of blood being sufficient to permit the deposition of fibrin in the sac, which is already favoured by inequalities in the surface of the sac and other causes. Nevertheless it must be borne in mind, that the more completely the current is suspended, the more quickly will coagulation take place in the sac, and the more speedy, as well as more certain, will be the cure. I do

* In a recent discussion at the Medico-Chirurgical Society, Mr. Cock is reported to have said, that he "had experienced some difficulty in applying the ligature after compression had been used, in one case, from thickening and absorbent inflammation over the sheath." I do not find any mention of this difficulty having been encountered in other cases of the same kind. Mr. Hewett has, in two instances, made most careful dissection, without discovering any thickening in the sheath or cellular tissue surrounding the vessels. In one case dissected by Dr. Bellingham, where pressure had been applied for twenty days, when the patient died suddenly from disease of heart, there was "some slight thickening of the cellular tissue around the vessel, at the situation where the pressure had been made, but no alteration whatever in the vessel itself." In two other cases there was nothing to indicate the points at which compression had been made; and in a fourth, the artery above and below the aneurismal sac is said to have been healthy.

not think that this point has been sufficiently attended to in the treatment of aneurism by compression. So much has been said about its being requisite only to moderate the force of the arterial stream, that surgeons have been content in many cases with applying very slight pressure, have thus prolonged the treatment over an unnecessary period, and have sometimes failed to produce the desired result altogether. This at least has, I believe, been the the case in most instances where so much time has been required to effect a cure; or, what amounts to the same thing, the instruments have been clumsy and insufficient, or the patient intolerant of pain.* Surely more numerous and more speedy cures would be obtained, and the new treatment would lose some of the reproach which now attaches to it, if the attempt were made in each case to carry it out more vigorously and effectively. In doing this, great care and great attention is required. Two, or even three, tourniquets should be used, so as to distribute the pressure over a greater surface, and to permit of a variation in the points at which it is applied. The instruments should be well adapted, and the surgeon should visit the patient frequently to adjust the apparatus, and regulate the pressure. If it can be done, without giving much pain, the pressure upon the artery should be maintained with such force as completely to stop the pulsation in the tumour; and great pains should be taken to effect this. If that cannot be done, we should endeavour to effect this, as nearly as possible, by maintaining as much pressure as the patient is able to bear. In a great number of the recorded cases no mention is made of the amount of pressure employed; but so far as I have been able to gather, the cures have been far the most expeditious, and on the whole the least painful, where the surgeon has made it his object not merely to *moderate*, but to *stop* the pulsation of the aneurism.—*Prov. Med. Jour.*

EFFECTS OF CHLOROFORM ON MUSCULAR CONTRACTION.

By William Barlow, M.R.C.S.,
Resident Medical Officer to the Westminster Hospital.

It has been shown by Nysten, in his ingenious researches, that a long time intervenes, as a general rule, between dissolution and this peculiar rigidity, during which time the muscles remain irritable; and that the rigor does not approach until the muscular irritability is either completely or nearly extinguished. This is, of course, a main fact. All kinds of muscular action prove the irritability of muscles, except rigor mortis; this, on the contrary, is a form of contraction which prevails not until muscular irritability is lost. After *excessive voluntary* action, such as that of the hunted animal, which though exhausted to the utmost, still runs for life, and forces to contraction muscles become almost too languid to respond effectually to any stimulus, however violent, rigor mortis has been commonly noted to ensue with unusual rapidity. As Nysten says, "c'est parceque l'action vitale du liévre que le chasseur a forcé est, pour ainsi dire, epuisée par une fatigue excessive, que, cet animal se roidit en mourant." So, too, *extreme involuntary* muscular contraction has been known to lead to the swiftest possible death-rigor. And it is very probable that the exhaustion of muscular irritability after death by galvanism would be found to hasten the phenomenon.

These things considered, what would seem more probable than that *any* agent possessing the power of lessening or destroying muscular irritability should have also the property of expediting rigor mortis?

Now nothing so rapidly and effectually subdues this irritability as chloroform; and it has been observed, that animals destroyed by it have become almost instantly rigid. I have watched frogs die most speedily from its vapour, and in these, after death, have failed to produce muscular action by a galvanic force which might have been expected to powerfully operate; in this state rigidity rapidly came on. Death by chloroform is peculiar; it is most rapid, but in every sense most absolute; let it be compared to other forms of dissolution which leave the muscles unimpaired in irritability, and wherein rigor mortis is long deferred. Do *human* subjects who die of chloroform stiffen with unusual rapidity? It is most important that this question should be answered. This case may be imagined: a person might be destroyed by chloroform, and being found rigid, a medical practitioner might *consequently* infer that death must *necessarily* have happened some hours. I need not say that in many kinds of medico-legal inquiry the *time* of dissolution is a principal point on which acquittal or conviction turns.*

How long might the body of the deceased have remained warm is an occasional question raised in investigation. But, under other circumstances, the inquiry might be,—how long may rigor mortis be deferred? or how rapidly may it happen? It would be as well to ask ignorance itself as a medical witness, considering the too neglected subject of rigor mortis for the first time.

But let me proceed to the experiments, which are very simple:—

I. I took a frog and wrapped it in wet lint, quite covering every part except one of the lower extremities. This I put into a glass tube, at the bottom of which were a few drops of chloroform, so that the limb was freely exposed to its vapour, which was of course prevented from escaping. In a very few minutes the limb was in a state of most perfect rigidity, and looked much as in confirmed rigor mortis. Then I withdrew the leg and uncovered the animal. It was somewhat drowsy from the narcotic; but yet it was obscurely conscious, and crept languidly along, trailing after it the rigid limb, which looked like a dead thing attached to a living. The part was, I need hardly state, quite anæsthetic and lost to volition.

II. I repeated the experiment with the same result, so far as producing rigidity was concerned; but the animal was so affected as to be unconscious. Soon after it appeared about to rally, but breathed at very distant intervals, and in the end relapsed and died.

III. A frog was decapitated, stripped of its skin, and exposed to chloroform vapour. The muscles gradually started into full view, the toes became outstretched and separate, and perfect rigidity ensued in less than four minutes.

IV. A frog was exposed after the same manner to the vapour of ether. The result was similar, but more gradually effected. It was observed that the muscles on both sides were *symmetrically* influenced, precisely as they are always in rigor mortis.

In these experiments the heart remained still pulsating after the removal of the head; and the chloroform to *some extent* circulated through the blood, though, from the hæmorrhage and shock sustained, feebly. But the continuance of the circulation was by no means *necessary* to the production of that influence of chloroform on the fibre which I would here exemplify: on the contrary, we may believe rigidity to be retarded even by a slow and feeble blood-current. In the following instances the heart was removed, after decapitation, before the chloroform was employed, in order to show more fully the *direct* influence of this agent on the muscular fibre. The spinal marrow was also destroyed previous to the trials.

V. A frog—the brain, spinal marrow, and heart being removed—was divested of its skin completely. I then placed one of the lower extremities in a glass tube and

* Doubtless, as Mr. Paget suggests in his remarks upon a case lately published in the *Medical Gazette*, the particular form of aneurism, whether it be "saccular" or "tubular," must have great influence on the facility with which coagulation of its contents will be brought about; the uniformity of the dilatation in tubular aneurism being very unfavourable to such a process. But this is not sufficient to explain the lengthy periods consumed in the treatment of popliteal aneurism by compression in so many cases, because the "tubular" form of aneurism is very rare in the ham.

* Dr. A. Taylor was very lately examined on this matter at a most important criminal trial, the issue of which was very much determined by his able evidence.

exposed it to the vapour of chloroform. It became almost instantly rigid, whilst the remainder of the body continued as lax as possible. It is of consequence to note that the vapour acted far more rapidly in this instance than in a former one, *in which the same part of the perfect animal, with the blood still circulating through it, was similarly treated.*

VI. The same experiment was repeated, and with the anticipated consequence. It was curious to watch the *distinct movements* induced by the establishment of the rigidity. First one toe was extended, then another, then the next, and so forth, until the web of the foot was put wholly on the stretch.

The change of position which may be found to take place from the occurrence of rigidity is very remarkable; and its degree is greatly or altogether owing to the swiftness with which the irritability is destroyed, and the rapidity and violence wherewith the rigor happens. In the following experiment, wherein a perfect frog was exposed to chloroform, that the degrees whereby rigidity approaches might be watched, the alteration of attitude was extremely striking. In order that such alteration may be seen to the full, the hind legs of the animal should be flexed during the period of its becoming rigid.

VII. A frog was exposed to some chloroform vapour: soon it became unconscious; but, on narrowly observing it through the glass covering under which it rested, I could every now and then see the faintest possible respiratory movement, and also trace occasional, languid beatings of the heart. Soon the latter were hardly discernible from their weakness, and the circulation must have been brought to extreme feebleness; and then I observed a slight movement of a lower extremity, quickly repeated, which gave notice of the commencement of rigor mortis. In a minute or two the pulsations were altogether imperceptible, and probably had ceased, and the manifestation of rigidity became much plainer. Peculiar, slow movements were seen from time to time; and it might, at least, have been thought that their effect in altering the posture of the frog would be insignificant. But it was far otherwise: soon the extensors became quite rigid, and so contracted that the bent legs became straightened to the utmost; and the toes, which lay side by side, were seen to diverge and expand to full tension the web between them. The head was drawn upwards, and the spine arched as in opisthotonos. The whole position would have seemed changed by some one sudden and violent spasmodic action, had it not been noted accurately to be the aggregate effect of movement following movement.

I have only performed one or two experiments on warm-blooded creatures, with the view of producing the same kind of muscular contraction after the cessation of the circulation.

VIII. A recently killed sparrow was stripped of its skin, and exposed to chloroform vapour. I was prevented from observing the effect of the trial for three-quarters of an hour; but, at the expiration of that time, I found the bird most completely rigid.

IX. The leg of another destroyed sparrow was exposed to chloroform vapour: it became rigid in three minutes.

X. A mouse, decapitated, deprived of its skin, and suspended in the vapour of chloroform, was made quite rigid in about ten minutes. A very gradual but most evident alteration of the position happened, and the spine was arched forwards in a striking manner.

In performing these experiments I have suspended the animals in a glass jar where I wished to affect all the muscles, and employed a common test tube where I only desired to influence those of a limb. The vapour of about half a drachm of chloroform will be quite sufficient so to impregnate the air of a closed quart-jar as to bring about the condition described; but the celerity with which it happens bears, of course, a due relation to the amount of the vapour, which, when much concentrated in a test-tube, will be found to act very rapidly.

It can hardly be necessary to observe that the form of contraction thus produced by chloroform is to be well distinguished from that rigidity of muscle which commonly takes place from the administration of this agent during surgical operations. The former implies the *loss* of irritability, whilst the latter distinctly denotes its *presence*; the former is always a persistent, whilst the latter is oftentimes a most transient act; in the former the fibres are seen to be affected universally and alike, whilst in the latter the action is often extremely partial; the former is constant, and can be produced at will, whilst the latter is of uncertain event, and cannot be occasioned at the wish of the experimenter; the former is a purely *physical* effect, whilst the latter is frequently of *psychical* origin, being due to the emotions of dreaming, or delirium, or of the waking state. But it is superfluous to pursue the obvious contrast: for life and death are not more different than these two kinds of muscular contraction.—*Med. Gaz.*

ON SANTONINE.

By G. W. Patterson, M.D.,
Physician of the Northern Dispensary of Philadelphia.

Having recently made free use of santonine for the expulsion of the *ascaris lumbricoides*, I desire to express the satisfaction which I have had from its employment, being in a concentrated form, and possessing neither taste nor odour, qualities which at least should be sufficient to give it some claims to consideration.

As an anthelmintic, it has a special mortal action upon lumbricoid worms. This I infer to be the case, from the fact that while it has failed in my hands when used *against tænia* and the *ascaris vermicularis*, it has rarely done so when there has been sufficient evidence of the existence of the *common round worm* to warrant its use.

Whether the presence of such parasites in the alimentary canal is deserving of the notice or regard of physicians, which some seem to deny, it is not my purpose at present to consider; but as there are those who do believe them to be a source of annoyance, and especially to children, I would recommend a trial of this vermifuge. It is a medicine that at one time had a considerable degree of celebrity; but, from some unknown cause, it is at the present time but little employed. It is somewhat expensive, and the articles which I used were presented to our institution by Messrs. Powers and Weightman, chemists of this city.

I am in the habit of prescribing it in the following manner, say to a child four years of age:—℞ Santonine gr. xii.; pulv. g. acaciæ gr. vi.; m. et in chart. iij. div. One to be given night and morning, and followed by a dose of fluid ext. of senna. I have been informed, in some instances, that worms were expelled before the cathartic was given, still I consider its administration desirable, serving to discharge that superabundant mucus which is usually an attendant upon such cases. The subsequent administration of the syrup of the citrate of iron, I have usually found will correct that state of the system which is so favourable to their production and multiplication.

Those who may use this medicine for the first time will probably have their attention directed to the colour of the patient's urine, the santonine having caused it to assume a saffron hue. This is not the result of irritation, which I have never known it to produce.

While in the choice of remedies, it should be our object to select such as are the best suited to meet the indications presented to our notice, we should never lose sight of the fact that medicines are, for the most part, repulsive to persons in a state of health, and become even more so when suffering from morbid derangements; that it is our absolute duty to administer them in as palatable a form as possible, and always to prefer such as are insipid or inodorous when no benefit can be obtained by a different course. I have had frequent occasion to witness the embarrassment which practitioners have experienced from want of attention to this matter. Entertaining such views, I have been prompted to make use of santonine as an anthelmintic, with which, after a fair trial, I have every reason to be pleased.—*New Jersey Medical Reporter.*

ULCERATION OF APPENDIX VERMIFORMIS.

W. H——, aged 26, a waterman, of spare make, pale complexion, and of industrious and temperate habits, was admitted into the London Hospital June 16, 1831, under the care of Mr. Luke. He complained of much pain in the abdomen, which he embraced with his hands; his countenance was anxious, and he moaned very much; he passed urine with great difficulty, at long intervals and in small quantity, although there was a constant desire of evacuating both the bladder and rectum.

The patient could not assign any cause for his illness, excepting that a day or two before admission he had had an attack of diarrhœa, and suffered much from tenesmus while at stool. He had taken a small dose of castor oil on the previous day, but the stomach had rejected it. For the last few weeks there had been much irregularity of bowels, and the present illness had come on suddenly.

He was placed into a warm bath, and afterwards into a warm bed; and when seen, in the space of an hour, expressed himself as much easier, and conversed cheerfully. On making an examination, the abdomen was found tense, and resonant on percussion, the sound being loud along the course of the ascending and transverse colon. *Firm pressure* gave some degree of pain in the right iliac and lumbar regions, and deep-seated uneasiness was felt about the umbilicus. The patient seemed to experience relief from the pressure in some parts, and never objected to it. Pulse full and strong, beating about 90; tongue moist, and slightly coated in the centre.

Mr. Luke ordered five ounces of blood to be taken from the right lumbar region by cupping, and a gentle dose of castor oil to be administered. The night was restless; the legs were drawn up in the morning, and the bowels still constipated; the oil had been rejected, and only two or three ounces of high-coloured and turbid urine had been passed. Saline medicine was now ordered; but as no amelioration took place on the next day, eight leeches were placed on the lower part of the abdomen, and a full dose of laudanum administered. This treatment was continued, and two days afterwards the patient seemed much better; he wished for some beer, and to be allowed to rise. Vomiting recurred soon after this, but several stools were passed, and the tension and resonance of the abdomen diminished. These favourable symptoms were not, however, of long duration; the patient became gradually worse; all the former signs returned, though pain in the abdomen was no longer complained of; and he died six days after admission.

Post-mortem examination.—Body pale and features contracted; the head was not examined, but the thoracic viscera were found healthy. On opening the abdomen, much fœtid gas escaped, as also a considerable quantity of serо-purulent fluid, in which several flakes of lymph were diffused. The peritoneum was much thickened, and rough with deposition of lymph, and the omentum covered by a layer of thick, cream-coloured pus and lymph, and firmly glued to the intestines. On breaking down the adhesions, and reflecting the omentum, the distended intestines were exposed; they were glued together by pus and fibrinous exudation.

On tracing out the convolutions of the small intestines to the termination of the ilium into the cæcum, the latter and the extremity of the ilium were found surrounded by fibrine, and the appendix vermiformis much enlarged and covered by the same exudation. Close to the origin of the appendix a small quantity of clay-coloured fæces were observed lying in the pelvis, surrounded by a large quantity of fibrinous matter. Several smaller portions of feculent matter were found within and around the appendix, and that process presented a *perforation*, evidently resulting from ulceration, which readily allowed the passage of the little finger. This solution of continuity existed at about three-quarters of an inch from the cæcum. The latter intestine was highly congested, its lining mucous membrane much thickened and of the colour of coffee-grounds. The ileo cæcal valve was perfect, but the opening of the cæcum into the appendix evidently defective. The intestines generally contained but little feculent matter, and the remaining abdominal viscera presented no evident alteration, though they were thickly coated with the fibrinous exudation which was pervading the whole cavity.—*Lancet.*

COUP DE SOLEIL.

By Drs. Pepper and Condie.

Very erroneous notions respecting the nature of this affection prevail. Twenty patients have been admitted on account of it into the Philadelphia Hospital in seven years, of whom seven recovered, ten died, and three continued to suffer from chronic disease of the brain; all these persons having been bled prior to admission. The prominent symptoms are violent convulsions, with muscular tremors in the intervals; a small, thready, irregular pulse, and dilated pupil. Dr. Pepper has of late had the opportunity of witnessing four autopsies (from six to eight hours after death), at which there was found no congestion, or other unusual appearance of the brain; but in all the heart was pallid, flaccid, and softened, though the other muscles were florid and firm. Its lining membrane (and that of the bloodvessels) was of a dark purple colour; its cavities contained little blood, and no coagulum. Similar appearances are described by M. Louis as occurring in typhoid fever that proves rapidly fatal. Apoplexy may occasionally, as it is too generally supposed to do, result from insolation; but the cases usually met with in hot summers bear no resemblance to it, and require stimuli instead of depletion. In all the fatal cases Dr. Pepper has met with, death occurred in six hours, and in the others recovery was slow, the mind continuing long in a confused state, and the case sometimes passing into one of insanity. The accident usually occurs to persons laboriously employed while exposed to the sun's rays. Muscular exertion and excessive heat, combine to stimulate the heart to morbid activity; copious perspiration and fatigue ensue; the organ becomes exhausted, and a passive congestion of the capillaries of the body occurs. It is a disease of nervous exhaustion, to be carefully distinguished from the cerebral congestion occasionally arising from the same cause. Of five cases treated by stimuli, three recovered and two died.

Dr. Condie observed, that the cases thus described are of common occurrence during hot summers, in persons engaged in laborious occupations, while exposed to the sun, and especially in those of intemperate habits. There is, however, another class of cases due to the same cause, in which the head, and often the entire surface, is intensely hot, the eyes are injected, the pupils contracted, the pulse small, quick, and corded, and the tongue red and dry. Such patients are delirious, morose, or constantly agitated; and if the acute meningitis, upon which these symptoms depend, is not treated by depletion, they die comatose.—*Amer. Jour. of Med. Sci.*

Tracheotomy in Œdema Glottidis.—M. Séstier has published a paper in the *Archives Générales* urging the earlier and more frequent resort to this operation in suitable cases. He gives an analysis of 138 cases of œdema glottidis, in 36 of which the operation was performed, with the result of preserving life in 13 and materially prolonging it in 8. He has also ascertained that the success of the operation very much depends upon the previous healthy state of the larynx, and recommends it chiefly in such cases, but does not consider it contra-indicated where prior disease has been known to exist, unless it be of an advanced stage and incurable character. As regards the time of performing the operation, M. Séstier would not be precipitate; as in several apparently very severe cases the disease has been got under by vigorous treatment. But, on the other hand, he counsels against waiting until no other chance is evident. He is guided by the amount of suffocative dyspnœa, together with feebleness of respiratory murmur. With reference to the operation itself, the author gives the preference to crico-tracheotomy. It is easier than tracheotomy, and less likely to be followed by the entrance of air into the veins, or of blood into the trachea.

EFFECTS OF CONCUSSION OF THE SPINE.

By J. Grantham, F.R.C.S.E.

The spinal column, considered mechanically, is weakest at the convex portion—that is, in the upper part of the cervical vertebræ, and from the tenth dorsal to the third upper lumbar vertebræ; the ten upper dorsal vertebræ are particularly defended from the influence of shock or fracture by the ribs and sternum, but when there is a yielding in the dorsal vertebræ, it will be found to occur at the centre of the arch or greatest convexity of that portion of the spine, which is between the fifth and sixth dorsal vertebræ. The purport of this paper is to detail the symptoms and effects of a shock of the spinal column. Concussion is conveyed to the spine when the patient falls from any height; whether the fall be on the head, or feet, or side, the back will receive a proportionate amount of the injury.

The first symptoms will be an inability, with pain, of movement in some part of the muscular structure pertaining to the spinal column. It is in the intervertebral structure of the spine where the first effects of lesion take place; and it would be enough for Mr. Grantham to direct the eye of the anatomist to the strong mechanical arrangement of the bones and ligaments, when it will be at once perceived how admirably the bodies of the vertebræ are held together, so as to render it almost impossible for any movement to take place apart from that of a general yielding. It will now be readily seen, that, should inflammatory action be commenced in this structure (intervetebral), and the body be allowed to remain in the erect position, pressure will be made on the seat of injury, pain will be felt, and *waste must ensue*; and for the sake of rendering this statement more evident, it may be well to consider the nature of the intervertebral substance. It is lowly organized, having neither vessels nor nerves; the cellular tissue does not become apparent; this cartilaginous structure contains a great quantity of water or serous fluid; according to Beclard, "in the adult man the proportion of water which they contain is to the solid substance as two and a quarter to one." The cells of this cartilaginous structure are very different from those occurring elsewhere in the animal organization—they are irregular in size and shape; in the condensed margin of the intervertebral structure, the cells are compressed, and lie with their long axes disposed parallel to the surface. It is said cartilage does not readily become atrophied by pressure. The author presumes this observation must have the condition stated—namely, when in a normal state; but if otherwise, or according to Bichat's nomenclature, it be "organically sensible," then he inferred atrophy or waste would be the result of pressure, as the reparative law of this structure would necessarily be imperfect, as every morbid phenomenon must in this structure be characterized by a remarkably slow progress; that inflammation must, as in bones, assume a chronic type, and should a cartilage be divided, in contradistinction to the skin or muscles, it closes instead of separating; the edges of their sections are drawn together; they never distend or lengthen. The absence of ossification in cartilages proceeds solely from the laws relating to the nutrition of bones. Here Nature has placed the limits for the exhalation of the calcareous phosphate, as she has also restricted to the origin of a tendon the exhalation of fibrin. The nature of the articulation of the vertebræ is of a mixed character, named Amphiarthrosis, partaking of the nature of Synarthrosis, in having the articular surfaces united by means of an intermediate substance, and of that of Diarthrosis, in having a considerable extent of mobility. Therefore, should the primary symptoms of concussion of the spine be unobserved or unattended to by either the patient or surgeon, partial paralysis will ensue, and be succeeded by complete paralysis below the injury or seat of lesion; the difficulty of movement will increase, until the formidable character of the malady will be evident to the most common observer; and, on examination, it will be found there will be an angular curvature of the spine, which can only arise from defect in the intervertebral substance.

Secondly. The assimilative laws of life will be functionally deranged. MM. Becquerel and Rodier state their is invariably a marked diminution of the quantity of the blood-corpuscles in the blood in injury of the spinal cord. The author has found in such injuries an elimination of the triple phosphates with the oxalates in the secretion of urine. The most important indication in the treatment of such cases is to relieve the injured part from the superincumbent weight of that part of the spine above the seat of lesion, by attention to the general health, and by an active *continued* application of counter-irritation to the region of pain. The author is an advocate, and has had some experience in the use, of the prone position as a mode of giving rest to the spine. He ventures to affirm four months is generally long enough to effect whatever good perfect rest of the spine can produce; but the most important and most difficult measure to be adopted at this part of the treatment, is being enabled to give the spinal column that kind of mechanical support which may be so applied as to gradually regulate the return of pressure, and at the same time to be sufficient for maintaining the erect position of the body for the restoration of the previously lost muscular support.

It is much to be regretted the great expense of the apparatus needful for these cases prevents their more frequent use; and may it not be narrow policy on the part of our rich hospitals that such cases are considered inadmissible, unless application is made soon after the injury is received?

There is one question which remains unsettled in the minds of the profession—viz., is it possible to have anchylosis of the bodies of the vertebræ without caries? If so, when the intervertebral structure becomes absorbed, then ossific matter will necessarily be generated without fracture: a fact of great importance as regards the favourable issue of lesion of the intervertebral cartilages. This question bears some analogy to the one regarding the union by bones of fracture through the neck of the femur.

The more the author reflected on the necessity of removing pressure or weight, when there may be any injury pertaining to this lowly organized structure, and maintaining a protracted state of quiescence in the early part of the treatment of concussion of the spine, the more was he convinced of the great importance of attending to this injunction.—*Med. Gaz.*

REVIEWS AND NOTICES OF BOOKS.

ON THE PRESERVATION OF THE HEALTH OF WOMEN AT THE CRITICAL PERIODS OF LIFE. By. E. J. Tilt, M.D., Senior Physician to the Farringdon General Dispensary and Lying-in Charity, &c. &c. London. 1851. 12mo. pp. 142.

Dr. Tilt is already favourably known to the profession by an excellent and original treatise on the "Diseases of Menstruation and Ovarian Inflammation." For some length of time he has been engaged, he states, "in collecting observations relative to the *natural history* of the functions peculiar to women, convinced that a more minute investigation into the phenomena of the healthy performance of these functions would throw light on the causes of disease, and promote their prevention and cure."

The present essay is founded upon a series of papers "on the right management of women before, during, and after the cessation of menstruation," communicated by Dr. Tilt to the *Provincial Medical and Surgical Journal*. It commences with a chapter upon the "right management of young women before the first appearance of menstruation.' The symptoms which indicate the approach of the menstrual flow are first given, followed by a table of the period of first menstruation in 11,429 women, in hot, temperate, and cold climates. These statistics are somewhat at variance with those of Dr. Roberton upon the same point, and they show that the first appearance of menstruation is influenced more by climate than the latter author is willing to admit. This table is followed by another, from which it appears that men-

struation occurs earlier in girls belonging to the higher classes than in the humbler ranks of society.

Dr. Tilt next makes some judicious remarks upon the danger of the administration of drugs by parents or other non-professional persons, in order "to force the first appearance of the menses." The author is of opinion that "the period of the first menstruation may be retarded in many girls much beyond the average age, and often without producing ill-health, or the slightest inconvenience."

"As the importance and relative value of a living being may be estimated by the length of time it takes to attain perfection—a criterion which gives us a high estimation of the value of man, who requires so many tedious years to achieve the fulness of his permitted power—I may reasonably propose what, on the other hand, the study of diseases of women leads me to infer—that the longer the reproductive apparatus lays dormant in women, the stronger will be their constitution, the more harmoniously will its functions be performed, and the more favourable will be the influence of this apparatus on the whole system.

We constantly hear parents talk of 'bringing girls forward,' but all my observations, reading, and meditations on the subject, confirm me in the opinion which I have long entertained, that the art of educating girls in order to bring them to the full perfection of womanhood, is '*to retard as much as possible the appearance of first menstruation.*'

If there be any possibility of effecting this purpose, it must be by maintaining in its integrity an essentially English institution—*the nursery*. The nursery, in the usual acceptation of the term, means rational food, rational hours of rest and of rising, and rational exercise at judicious times. It means the absence of sofas to lounge on; the absence of novels fraught with harrowing interest; it means the absence of laborious gaiety, of theatres, and of operas; the absence of intimacies which are of a too absorbing nature, and a wholesome subjection of every minute to rule and discipline."

The second chapter of Dr Tilt's essay is devoted to the "right management of women at first menstruation, and during the continuance of that function;" and the third to the "right management of women during matrimonial life." In the latter, the occasional occurrence of menstruation during pregnancy or lactation is considered; followed by rules "relative to the weaning of infants on the occurrence of menstruation, or during illness."

The "management of women at and after the cessation of menstruation," forms the subject of the next chapter. In it the author has given several tables illustrating the morbid phenomena by which the cessation of menstruation was ushered in, or accompanied, in 100 cases:—

"With respect to the quantity of the menstrual flow,

It terminated gradually in	39	per cent.
,, by a succession of floodings in	19	,,
,, by a terminal flooding in ...	14	,,
,, by alternations of a little, and a considerable flow in ...	10	,,
,, by a sudden stoppage in ...	18	,,
Leucorrhœa had existed in	58	per cent.
,, it was augmented in ...	44	,,
,, was stationary in	8	,,
,, was diminished in	6	,,
Diarrhœa existed in	12	per cent.
,, it was irregular in	8	,,
,, was regular by coming on every month in ...	4	,,

When diarrhœa occurs at the change of life, it generally appears at irregular intervals; it may, however, adopt the regularity of the menstrual function. . . . . As a general rule, however, when diarrhœa has habitually accompanied menstruation, there is at the change of life a gradual diminution of both discharges, the cessation of the one marking the termination of the other."

The last chapter is devoted to the "treatment of diseases at the change of life;" the following are the principal contents of this chapter:—

"Utility of bleeding at the change of life shown by the natural history of menstruation; cases; manner and amount of blood-letting; utility of leeches exemplified; utility of outward application of sedatives; alkaline preparations justified by the frequent morbid state of the urine at the change of life; the state of the urine previous to each menstrual epoch a new field of inquiry; the utility of purgatives suggested by the natural history of the change of life; mode of exhibition of purgatives; utility of sulphur; local treatment; statistics of leucorrhœa occurring at the change of life and its prognosis; mineral waters, and proposition relative to their employment; conclusion; rules of conduct, the inculcation of which by the profession would be useful to society."

Although numerous treatises are in the hands of the profession in which the diseases of females are fully considered, we are not aware of any devoted exclusively to the prevention of these diseases. Dr. Tilt, in the essay before us, has entered upon this hitherto almost untrodden path; we hope that he may follow up the subject, as, from the specimen he has given, it could scarcely have fallen into more able hands, and we trust to meet him again in the same field of inquiry.

DUBLIN: WEDNESDAY, NOVEMBER 5, 1851.

MEDICAL EDUCATION.

The vexed question of medical education and its objects seem about to have a practical solution. Be the cause what it may, shadows are no longer held sufficient guides or leaders, and men seek substantial agents to secure substantial results. Wigs, caps, gowns, and hoods, which once so fascinated the world, no longer serve to relax a purse-string, and we of the healing art seek more potent means to convince the sceptical that we are of the realities. Without act of parliament or royal charter, but rather regardless of them, men seeking a livelihood from the practice of our profession prepare, as if instinctively, to meet this new state of things, and hence the present disrelish for empty titles, and the strong desire to secure more convincing proofs of positive qualification. No law has been made, no practice pursued, which forbids or discountenances the taking of medical degrees in universities, yet it is evident that this ancient method of establishing a claim to medical character is rapidly falling into disuse. The guardians of the fountains of "medical honours," and those who at the present moment are anxious to draw from them, may be startled by such an assertion, but it is nevertheless a true one. For general practice or public employments, it is now admitted on all hands, a degree or licence merely medical is no adequate qualification. Pure Physicians are required in large towns, and appointments are reserved for them in large hospitals, but General Practitioners they cannot become, neither can they well be appointed Medical Officers to Workhouses or Dispensaries. We do not deny that there are physicians in good practice, and in the care of public institutions, labouring successfully and creditably, but these have been created by a system now obsolete, and for a state of society which has disappeared. Now, be he what else he may, a man must be a Surgeon to occupy such a position, a Surgeon *de facto* and *de jure*. A physician with such a smattering of surgery as universities and medical colleges can afford will

not answer; the public and the authorities call for an accredited Licentiate of a College of Surgeons. This is a remarkable result. Sixty or seventy years ago there were few regularly educated surgeons in Ireland, or even in England; so much so, that in 1784, a sufficient number of respectable practitioners in this department could scarcely be mustered to found the College of Surgeons of Ireland: while now this College alone includes about a thousand members within its government and protection. But the advocates of institutions merely medical will retort that, although a man must be a surgeon for general practice and the care of our mixed medical charities, he must also be a physician; which we admit to the extent of conceding that he should be as well acquainted with diseases called medical as those called surgical. We do not, however, admit that he should be compelled to seek a nominal title to establish his right to treat these so-called medical diseases, especially from bodies which have no authority to grant anything but a title. After a surgeon has had an ample surgical education, and, in addition, a medical one, fully equal to that required for a medical degree or licence, it would be a great hardship to him, at much expense of time and money, to be subjected to a compulsory repetition of that education. In England the qualification for general practice and public appointments is a surgical diploma and a licence from the London Apothecaries' Company, in consequence of the College of Surgeons of England declining to examine candidates in medicine and pharmacy; but in Ireland the College of Surgeons enforces a full medical education, and examines as strictly in medicine and pharmacy as any medical college. Formerly many surgeons in Ireland sought medical degrees because, having finished their surgical education, they found such an addition to their qualifications both useful and creditable, but now that little is gained in the way of instruction by such a course, and little in the way of character, they do not often do so; they cannot see the advantage of being lectured over again, and examined over again in surgery by men who hold exactly the same surgical diploma they themselves possess. In public estimation, too, the magical M D. has lost much of its value since it became notorious that it was to be had on very easy terms, and since it began to figure on the lids of pillboxes. So much so, that wise men begin to discover that plain "Mister" is a more attractive designation than the common title of Doctor. But medical reformers, and especially those of the "one-faculty" sect will say, "a plague o' both your houses," why not have a comprehensive diploma granted by some one body which shall declare the bearer to be fully qualified at all points? And why not, seeing that the thing is, as we have just said, virtually done by the College of Surgeons? The medical colleges, feeling the old medical ground going, like a quick-sand from beneath their feet, wax chirurgical, and threaten to tack *magister chirurgiæ* to the M.D., and why not let them try their hands in this way; M.D.C.M. would settle the matter. We must, however, cut short our cogitations touching these weighty questions, lest a recollection of former days, when grave doctors eschewed surgery as an unclean thing, should provoke our risibilities to unseemly explosion. In the meantime, it may be that while we write the gordian knot is severed. The piece which has lately been under rehearsal in the Medical Hall of Dublin Castle, and which is, we hear, cast for speedy representation, with new scenery, machinery, dresses, and decorations, may have such a run as will settle this matter for a season. What it may in the sequel achieve, when divested of its theological and political appliances, is another question. One word and we have done. We merely wish to suggest that the parties who so joyously announce the intelligence of their "recognition" by the managers of this new medical theatre, will, in return, for the special favour conferred on them, attend the first representation to display their gratitude. Some "nice pickings" in the shape of Professorships, Examinerships, Scholarships, and "Exhibitions," may from time to time drop, and it may be well to be on the spot to see where they may fall.

TRESPASSERS ON MEDICAL CHARITIES.

The change now in progress in Ireland with respect to the Dispensaries makes the following extract one of interest. The administration of gratuitous medical aid to persons not paupers, at dispensaries, is no longer lawful, and those obtaining it are liable to be called on to pay for it if discovered. Right or wrong this is now the law, and the sooner the surgeons of Ireland look to it the better, for out of such change will arise a new state of things. Guinea fees are out of the question in dealing with the parties who were heretofore quartered on the dispensaries for medical aid, but more moderate fees are not; and the moment has arrived when men must make up their minds as to the class of practitioner who is to enjoy them. Irishmen seem to have as yet to learn that there are twenty-one shillings in a guinea:—

That persons attend our public hospitals *in forma pauperis*, who are able to afford a fee to their medical adviser, is well known, and it is a difficult and painful task to detect amongst a number of patients those who would abuse the means thus offered for the benefit solely of persons not able to procure advice essentially necessary for the cure of specific disease. The particulars of the case are these:—A child was brought to the Kent Ophthalmic Hospital in the month of March in this year, under the care of a nurse, when she was at first attended to, and received advice and medicine. It was subsequently ascertained that her father was a large out-fitter at Chatham, and in good circumstances. It was then explained to the friends of the child the next time she was brought to Maidstone, that the hospital was established only for *poor and indigent* persons, and that she could not be received there, but must be attended to by their own medical man at Chatham; or if they wished to receive the advice of the surgeon of that institution, she must be placed under his care as a private patient, and attend at his house. The friends preferred the latter, and lodgings were taken in the neighbourhood of my residence. When the child returned home, I requested the payment of my fee for professional attendance—ten guineas. This not being sent after frequent applications, I determined upon endeavouring to protect the hospital and the profession from so glaring an evil as the passing by of this case unnoticed might give rise to. The case was tried on the 6th of October before J. Espinasse, Esq., in the county court at Maidstone, and it was attempted to be proved by the counsel for the defendant that he was not liable for the debt, the child having been entered on the out-patient's book of the hospital, and that the surgeon had no authority to say which should be hospital patients and which not; and further, that it was the intention of his client to give a donation to the hospital, not having authorized the plaintiff to treat his child as a private patient. The learned commissioner by whom the cause was tried, said that there could be no doubt that the defendant was fully aware that his child was attended as a private patient, for he acknowledged he had paid for the medicine prepared at a druggist's from a prescription given by the plaintiff, which would at once have assured him that the child was no longer an hospital patient; and he considered it a gross abuse for persons in the defendant's station of life to seek relief at a charitable institution.—Judgment for plaintiff.—*Mr. Woolcott of Maidstone in Lancet.*

UNIVERSITY OF ST. ANDREW'S.

Examiners for Degrees in Medicine.

George E. Day, M.D., F.R.S., Professor of Anatomy and Medicine.
Arthur Connell, F.R.S.E., Professor of Chemistry.
William Pyper, LL.D., Professor of Latin.
Andrew Anderson, M.D., Professor of Medicine in the Andersonian University, Glasgow.

The examinations take place twice in the year, commencing on the first Wednesday in May, and the third Wednesday in October. The graduation fee is twenty-five guineas. In the event of a candidate being found unqualified, he shall forfeit five pounds of the graduation fee; which however will be accounted for to him when he passes his examination at a subsequent trial. Candidates can only be admitted to examination at other periods by a special grace of the Senatus Academicus. The graduation fee in this case is fifty guineas. The examination extends over two days, and is conducted partly in writing, and partly orally. On the first day candidates are required to give a written translation of a passage from a Latin medical author, and are examined in the elements of chemistry, in materia medica, and in anatomy and physiology. On the second day they are examined in pathology and the practice of medicine, in the principles of surgery, and in midwifery. The degree is conferred on the following morning by the Rector, in the Hall of the Public Library of the University, and the diplomas are signed by the principals and professors of the University. Every candidate is required to present himself for registration to the secretary, on or before the day preceding the examination, and to communicate by letter with the professor of medicine, at least a fortnight previously, stating what diploma or certificates he intends to produce.

"*To the Rector and Senatus Academicus, University of St. Andrew's.*

We, the undersigned candidates for the degree of Doctor of Medicine in this University, having understood that our diplomas will probably be signed by the Professor of Civil History, who is an avowed homœopathist, and holding as we do the opinion that the doctrines of Hahnemann are utterly irreconcilable with common sense, and with those medical tenets in which we have been educated, and which we trust will ever guide our professional career, respectfully request of the Senatus Academicus that they will adopt such measures as they may deem expedient for the purpose of preventing that desecration of our diplomas which we consider would be inflicted on them if a homœopathic signature were affixed thereto.

John Brown, John Cowie, H. W. Watson, Edwin Humby, N. J. Highmore, Fred. Goodchild, George Miller, Charles Gibson, Thomas Torney, John Walling, C. D. Kingsford, Robt. Beales, T. J. W. Marsh, Alex. S. Fogo, John F. Gruie, John Pearson Nash, John Roulston."

List of gentlemen who had the degree of Doctor of Medicine conferred upon them, 17th October, 1851:—Robert Beales, L.A.C., London; John Brown, M.R.C.S., and L.A.C., Islington; John Cowie, M.R.C.S.E., Zetland; Alexander Scott Fogo, M.R.C.S., London; Charles Gibson, M.R.C.S., and L.A.C., Newcastle-upon-Tyne; Frederick Goodchild, M.R.C.S., Middlesex; John Frederick Grace, M.R.C.S., London; Nathaniel Jarvis Highmore, M.R.C.S., and L.A.C, Bradford, Wilts; Edwin Humby, M.R.C.S., and L.A.C., London; Charles Dudley Kingsford, M.R.C.S, Middlesex; Thomas Joseph William Marsh, M.R.C.S, and L.A.C., Surrey; George Miller, M.R.C.S., and L.A.C., London; John Pearson Nash, M.R.C.S., Calcutta; John Roulston, M.R.C.S., and L.A.C., Yorkshire; Thomas Torney, M.R.C.S.E., Dublin; Henry Uwins, M.R.C.P., and M.R.C.S., London; John Walling, M.R.C.S, and L.A.C., Yealand, Lancaster; Henry Waldron Watson, Arnold, near Nottingham.

ERRATUM IN THE STUDENTS' NUMBER.—The name of Robert Law Nixon was accidently omitted in the list of Examiners of the Royal College of Surgeons.

INSURANCE COMPANIES *v.* THE MEDICAL PROFESSION.

Royal Exchange Assurance of London,
8, Westmorland-street, Oct. 20.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—I have just seen an article in the columns of the last number of your journal, setting forth the resolutions of the Faculty of Physicians and Surgeons at Glasgow in reference to the payment of fees to medical referees of life assurance companies.

It may not, therefore, be deemed inopportune, now that the attention of the Irish faculty has been thus drawn to the subject, if I should state for their information, that the practice of the corporation of the Royal Exchange Assurance (one of the oldest life offices in existence) has been to pay the fees of the medical referees of *all* lives proposed to them for assurance; the scale adopted being *one guinea* where the sum proposed amounts to £500 or upwards, and *half a guinea* if the proposal be for any smaller amount; and when it is taken into account that the corporation have likewise to pay the fees of their own medical examiners, it must be admitted that they have not been illiberal to the profession.

In originally adopting the system (in which I believe they stand alone as a senior company), the Court of Directors were induced to expect the confidence and medical aid of the profession in the careful selection of eligible lives; and if same has not been fully reciprocated, they would fain hope that any reserve which may have occurred has been traceable rather to a misconception of duty towards their patients than from a desire to mislead the corporation.

Permit me to avail myself of this opportunity to remind the medical profession in Ireland, that the corporation have at all times acted with a degree of liberality towards them, as regards the assurance of *their own lives*, which has not been surpassed by any other company; in confirmation of which I would instance the occasion of the recent epidemic fever and cholera, when the doors of almost every other institution were closed against them, or terms so excessive required as to preclude acceptance on their part, the Royal Exchange Company freely entertained their proposals without charging *one farthing* extra premium.—I am, sir, your obedient humble servant,

THOMAS TROUTON, Agent.

MEDICAL SOCIETY OF LONDON.

AT a Special General Meeting of this Society held on Friday, October the 10th, the following resolutions recommended by by the Council were unanimously adopted:—

"That in the opinion of this Society, the practice of homœopathy, or the prescribing medicines in what are called 'infinitesimal doses,' under a pretence that they are useful in the cure of disease, is founded in palpable error, is a delusion on the part of the practitioner, a deception on the public, and manifestly dangerous to its welfare."

"That the Fellows of the Medical Society of London cannot honourably hold any professional communion with homœopathists."

"That consequently, any Fellow of this Society who shall hereafter practise homœopathy, or who shall knowingly meet in consultation any professed homœopathist, will thereby render himself unworthy of the Fellowship of this Society."

CLONLEIGH DISPENSARY.

AT a Meeting of the Governors of the Clonleigh Dispensary, held at Lifford, October 30th, 1851, the following resolutions were unanimously adopted:—

Resolved—"That the Legislature having placed the management of Dispensaries henceforth in other hands, we cannot resign our trust without bearing testimony to the professional skill and humane attention with which Wm. John Greer, M.D., has discharged the duties of Physician and Surgeon of this Dispensary for more than twenty-one years, within which eventful period it pleased God to visit us with cholera, fever, and the many diseases consequent on want."

Resolved—That as Trustees for the poor, and influenced by a regard for their interest, we recommend him to the favourable attention of those to whom these interests are now committed, trusting in any arrangement which may be made as regards districts, this locality may not be deprived of his services, and that in adjusting the scale of future remuneration, a more liberal salary may be awarded to him than our limited funds for many years enabled us to grant."

Resolved—"That we offer our warmest thanks to the Rev. John King, our Secretary, and George Knox, Esq., our Treasurer, for their gratuitous and valuable services."

B. G. HUMFREY, Chairman.
JOHN KING, Secretary.

PRACTICE OF PHYSIC.

DR. BENSON will commence the Course of Lectures on the Principles and Practice of Physic in the Royal College of Surgeons on Friday, the 7th day of November, at four o'clock p.m.

The Description, Pathology, Diagnosis, and Treatment of *Medical* Diseases will form the subject of the Course.

Pathological preparations, plates, and recent specimens of diseased parts, will be exhibited for the purpose of illustration.

The Lectures will be delivered on Mondays, Wednesdays, and Fridays throughout the session, at four o'clock.

N.B.—Gentlemen entering the Army are required to attend Two Courses of Lectures on the Practice of Medicine; and those entering the Navy to attend Three such Courses.

Fee for each Course ... ... Two guineas.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

THE COMPOUNDING DEPARTMENT
AT
G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their *unremitting personal attention;* to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. AND CO. CONTINUE TO BE SUPPLIED WITH THE FOREIGN MINERAL WATERS FRESH FROM THEIR VARIOUS SPRINGS.

☞ *Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

TYNAN DISPENSARY, COUNTY ARMAGH.

AT a numerous Meeting of the Governors, held in the Surgeon's House, Tynan, on Thursday, the 2nd day of October, 1851,

ACHESON ST. GEORGE of Woodpark, Esq., in the chair,

the following Resolutions were proposed and passed *nemine contradicente*:—

Resolved—"That the Governors of Tynan Dispensary, impressed with a deep sense of the professional ability, humane attentions, and unwearied attendance of their Medical Officer, Charles T. Huston, Esq., L.R.C.S.I., hereby tender to that gentleman the sincere and unanimous expression of their approval and warm congratulations on his well-merited professional position and prospects."

Resolved—"That the Governors cannot separate without recording their appreciation of the perseverance and energetic services of their respected Treasurer and acting Secretary, Thomas J. Tenison, Esq., whose untiring zeal and judicious management has mainly contributed to the present prosperous condition of the Institution."

ACHESON ST. GEORGE, Chairman.

Mr. St. George having left the chair, and Mr. Cross having been called thereto, it was

Resolved—"That the grateful thanks of the Governors are due and hereby given to the chairman, Acheson St. George, Esq., for his generous contributions to the funds, and uninterrupted support of this excellent charity during the last thirty-three years."

MAXWELL CROSS, Chairman.
THOMAS J. TENSION, Acting Sec.

SCHOOL OF SURGERY, ROYAL COLLEGE OF SURGEONS.

The Session 1851–52 commenced on Monday, October 27, at one o'clock.

Anatomy and Physiology—Dr. Jacob.
Descriptive Anatomy—Dr. Hart and Dr. Macdonnell.
Surgery—Mr. Porter and Mr. Hargrave.
Practice of Medicine—Dr. Benson.
Chemistry—Dr. Barker.
Midwifery—Dr. Beatty.
Comparative Anatomy—Dr Jacob.
Dissections by the Professors of Anatomy and the Demonstrators—Dr. Leeson, Mr. Labatt, Mr. T. D. Hargrave, Mr. Malcolmson, and Mr. J. Morgan.

Commencing May 3, by order of the College.

Materia Medica—Mr. Williams
Medical Jurisprudence—Dr. Geoghegan.
Botany—Dr. A. Mitchell.
Practical Chemistry—Dr. Barker.

The Fee for each of the above Courses is Two Guineas, except Comparative Anatomy, which is free.

A Public Course of Lectures on Comparative Anatomy and Zoology, free to all students, is delivered by the Professor of Anatomy and Physiology at the commencement of the session; and additional lectures on the same subject at intervals during the winter.

Practical Instruction in Operative Surgery is given by the Professors of Surgery, separate from the Surgical Lectures. Fee, £5 5s.

The Professor of Chemistry receives operating pupils into the Chemical Laboratory.

The Professor of Medical Jurisprudence gives practical instruction in Toxicology in his Laboratory.

The following Ordinance was made by the Council of the College on the 9th of April, 1851:—"To enable surgical students to devote more time to hospital attendance and dissection during the winter session, the lectures on materia medica, medical jurisprudence, practical chemistry, and botany, shall be delivered during the summer session in the School of the College, and in the schools recognized by the College; and certificates granted subsequent to the 30th of April, 1851, shall not be received as qualification for letters testimonial, unless issued in conformity with this regulation" Similar regulations have been adopted by the Council of the College of Surgeons of England.

In order to give full effect to this order, and to secure the advantages contemplated by it, no lectures will be delivered during the winter before one o'clock; from which hour the order of business will be as follows:—

Descriptive Anatomy, at one o'clock every day.
Anatomy and Physiology, at two o'clock every day.
Surgery, at three o'clock on Tuesdays, Thursdays, and Saturdays.
Chemistry, at three o'clock on Mondays, Wednesdays, and Fridays.
Practice of Medicine, at four o'clock on Mondays, Wednesdays, and Fridays.
Midwifery, at four o'clock on Tuesdays, Thursdays, and Saturdays.

Dissections from sunrise to sunset; one or more of the Demonstrators being always present to give instruction.

The Anatomical Instruction on Mondays, from one to three o'clock, will consist of practical instruction in the use of the Microscope, Minute Dissections of Organic Structure, and the making of Anatomical Preparations.

The Professor of Botany will commence a course of Lectures on Structural and Physiological Botany in February. This course, taken in conjunction with that on Comparative Anatomy and Zoology, by the Professor of Anatomy and Physiology, constitutes the Course of Natural History required by the Army Medical Board.

Pupils attending the Lectures on Midwifery and Diseases of Women and Children are admitted to the practice of a recognized midwifery hospital on payment of a fee of £4 4s.

CITY OF DUBLIN HOSPITAL,

Upper Baggot-street.

The Winter Session commenced on Monday, October 27th.

During the summer recess this Hospital has been greatly enlarged. Its arrangements are now such as to afford the student an opportunity of studying disease in all its forms—medical and surgical. The morning visit commences daily at half-past eight o'clock, when the nature, treatment, and progress of each case are explained at the bedside of the patient, and ample opportunity afforded to every student of becoming practically acquainted with the uses of the Stethoscope. Clinical Lectures are also delivered after the hospital visit.

Connected with the hospital is an extensive Dispensary, at which the pupils are allowed to perform the minor operations, under the guidance of the surgeons, and are rendered familiar with the details of dispensary management.

Every facility is given to students desirous of acting as Dressers and Clinical Assistants, subsequent to which all pupils of the hospital are eligible to the situation of House-Surgeon, according to merit.

A distinct Course of Lectures upon Diseases of the Eye is delivered by Dr. Jacob, and special wards are appropriated for the reception of Eye cases. Extended opportunities are thus afforded for acquiring a thoroughly practical knowledge of this important subject.

A ward is appropriated to the Diseases of Females, and clinical instruction is given upon all forms of Uterine Affection by Dr. Beatty.

Mr. Tufnell's Course of Lectures upon Military Surgery is also open to the pupils of the hospital. This Course is recognized in the professional qualification of candidates for admission into the Army, Navy, and Ordnance Medical Departments.

A Lending Library of well chosen books has been provided for the use of the pupils; and a correct registry of the cases in hospital is kept by the house-surgeon, to which they have free excess.

Certificates of attendance at this hospital are recognized by all the Colleges, Universities, and Halls, and by the Army and Navy Medical Boards.

Fee for Winter six months	...	Six guineas.
,, Summer six months	...	Four guineas.
,, Nine months ...	...	Eight guineas.

Physicians and Surgeons.

A. Jacob, M.D., F.R.C.S., Professor of Anatomy and Physiology, Royal College of Surgeons.
T. E. Beatty, M.D., F.R.C.S., Professor of Midwifery, Royal College of Surgeons.
C. Benson, M.D., F.R.C.S., Professor of the Practice of Medicine, Royal College of Surgeons.
W. Hargrave, M.D., F.R.C.S., Professor of Surgery, Royal College of Surgeons.
R. C. Williams, M.D., F.R.C.S., Professor of Materia Medica, Royal College of Surgeons.
T. G. Geoghegan, M.D., F.R.C.S., Professor of Forensic Medicine, Royal College of Surgeons.
J. Tufnell, Esq., F.R.C.S., Surgeon to the Military Prison.

Consulting Physicians.

Sir Henry Marsh, Bart., and Professor Apjohn.

Consulting Surgeons.

Sir Philip Crampton, Bart., Professor Porter, and J. W. Cusack, M.D.

For further particulars apply to Dr. Benson, 34, York-street.

DISEASES OF THE EYE.

DR. JACOB will deliver a full Course of Lectures on the Anatomy, Physiology, and Optical Mechanism of the Eye, during the ensuing Session, in the College of Surgeons, and also a separate Course on its Pathology and Diseases, with the Operations required in their Treatment, in the City of Dublin Hospital.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, Arthur Jacob, M.D., 23, Ely-place, in the City of Dublin. London: John Churchill, 46, Princes-street, Soho.
Wednesday, November 5, 1851.

LECTURES.

EXTRACTS FROM LECTURES DELIVERED AT VARIOUS TIMES IN STEEVENS' HOSPITAL.

By Sir Henry Marsh, Bart.

(Reported by Henry Freke, A.B., M.B.)

(Continued from p. 291.)

The following case of inodorous pulmonary abscess is, I think, an instructive one. The notes were taken and given to me by my young and talented friend Dr. Robert Macdonnell, whose ardent zeal in the prosecution of medical science has particularly attracted my notice. The presence in this case of an amphoric resonance distinguishes it from all other cases of the same kind which I have witnessed. It was signalized, too, by a slight attack of hæmoptysis:—

John Gillespie, ætat. 23, is a rather spare and pale man, but not in other respects of strumous appearance; he states that he enjoyed good health until about five months since, when he became affected with cough, muco-purulent expectoration, and general hectical symptoms, such as night-sweats, &c. In this state he continued, not getting much worse, and without seeking medical aid, until a month since, when he coughed up about an ounce of florid, frothy blood. A few days afterwards, while marching, he expectorated several mouthfuls of "corrupted matter." From that time to the present, he had no return of hæmoptysis, but he expectorates a large quantity of viscid muco-purulent, nummulated sputa.

On examining the chest, the right lung appears to be perfectly healthy, and the apex of the left offers no indication of tuberculous deposit or other disease. Over the lower part of the left lung posteriorly (from about its root to its base), there is a coarse gurgling crepitus, with slight but decided dulness on percussion, as compared with the opposite side, and marked increase of vocal resonance. In the apex of the axilla the respiration is quite natural; when we come down to the level of the nipple, most distinct amphoric blowing is heard, accompanying both inspiration and expiration; but the most careful examination fails to detect any metallic tinkling, succussion sound, or pectoriloquy. Neither is there any displacement of the heart or difference on percussion between this locality and the corresponding part of the opposite side. This remarkable amphoric blowing was some time inaudible for several days at a time, yet for more than a month occasionally returned with as much distinctness as in the most marked case of pneumothorax.

Gentlemen, if you seek for information on the subject of fœtid abscess of the lung in the writings of our ablest pathological authors, you will in general find but a scanty amount of information. If we were to seek to derive our knowledge from exclusively anatomical researches, we should be at fault; for in this as in many perfectly curable diseases, no trace of organic change remains for the eye of the anatomist. It is from experience, from the recorded facts of many practitioners, that we must hope to derive statistical knowledge. Simple non-tubercular abscess of the lung, then, is by no means so infrequent as some systematic writers would lead us to suppose. I have met with many cases of the disease; so have others with whom I have conversed. Long ago, I have repeatedly heard the late Dr. Perceval speak on this very subject. His history of this disease, though unaided by auscultation, was singularly accurate. He argued (guided principally by the fœtor) that the abscess was formed in the liver, and that the matter was (to use his own phrase) "pumped up" through the lungs. The late Dr. Cheyne, with whom, in more than one case of fœtid abscess I have held consultations, adopted the same view. Occasionally, not often, there is a difficulty in determining whether the abscess be seated centrally in the base of the right lung or in the liver. I remember having several times seen an interesting case of fœtid abscess with my friend Dr. Croker King, now Professor of Anatomy in the Queen's College, Galway. The illness was protracted for many weeks; great quantities of fœtid matter were expectorated; irregular hectic fever, emaciation, anorexia, sleeplessness, paroxysms of oft-recurring and harassing cough, resisted all treatment, and brought the patient in the meridian of life down to a premature grave.

The chest was repeatedly examined by the most able auscultators in Dublin, and no pulmonary disease could be detected, until about three days before death, when dulness and impermeability to air over a very small space at the base of the right lung seemed to indicate the locality of the disease. A post-mortem examination was not permitted. The evidence in this case appeared to me to favour the view of its having been an hepatic abscess.

The following reasons may, I think, be assigned for the supposed infrequency of non-tubercular pulmonary abscess. First, many recover so completely as to preclude anatomical information; when recovered from, it does not appear to interfere with future health and longevity. Secondly, when the disease (as I have shown) becomes chronic, changes may take place in the parenchyma of the lung, which may obliterate every trace of the primary abscess. Thirdly, when the fœtor is intense, cases of true fœtid abscess are described and named as gangrene or sloughing abscess of the lung.

There is not any variety of pneumonia less apt to terminate in gangrene than that which is single, circumscribed, and terminating in abscess; much more likely is the diffuse inflammation so to terminate. Yet one cannot be surprised at the mistake, so offensive in some cases is the odour. True gangrene of the lung I believe to be a comparatively rare affection; no case of fœtid abscess that I have seen has so terminated. Such may be the result, but I have not witnessed it. In the few cases of gangrenous pneumonia which I have observed, I cannot easily forget the alteration, rather suddenly wrought, in the traits of the countenance; the leaden, wild aspect, the suspirious breathing, the rapid, feeble, intermitting, flickering pulse, the clammy sweat, the putrid odour—all foretold that life must soon be extinguished. The few cases in which the opportunity has been afforded me to institute a post-mortem investigation, the putrified lung was all but identical in appearance with the putrescent areolar tissue in gangrenous erysipelas. The characters, too, of the morbid action, constitutional and local, the type of the fever, the uncircumscribed nature of the inflammation, establish a very striking accordance.

I saw a fatal case of gangrene of the lung in which the morbid appearances bore a considerable analogy to those of a large anthrax.

It happens now and again that, at the most advanced stage of phthisis, the internal lining membrane of a tubercular abscess is seized upon by gangrene, of which the putrid odour is very offensive. Mortification extends not more deeply than a few lines, and seems to be confined to the flocculent adventitious membrane with which the cavity is overlaid. Its softened, shreddy, black aspect, and putrescent smell, indicate this change; and also indicate that local death antecedes—but for a brief period of time—universal death. The system having been utterly broken down by preëxisting disease, such might be the close of a simple as well as of a tubercular abscess. There are other forms and varieties of pulmonary gangrene; these it is not my object at the present moment to dwell upon, nor would I have said even thus much upon the subject were I not anxious to impress upon your minds that the distinction, symptomatic, therapeutic, and pathologic, between fœtid abscess and gangrene of the lung is well-marked, and is one which, when you engage in practice, you ought not to discard from your minds.

Let me remind you, gentlemen, that fœtor is an attribute by no means limited to pulmonary abscesses; it is characteristic of many others in different regions of the animal frame. Abscesses situated where mucous glands and follicles abound, as the nares, fauces, vagina, rectum, emit frequently a most offensive odour; as also do those which are in contact with diseased bone—an odour which is modified and augmented by exposure to atmospheric air. Abscesses have been found in the brain, which, though unapproached by mucous membrane and untouched by atmospheric air, have emitted an intensely fœtid odour: a proof that contact with air is not essential to the production of fœtid emanations. It appears to depend primarily as well upon constitutional as on local causes. We find that during the progress of an illness it varies in intensity, and is sometimes intermitting. I remember having been consulted many years ago by a gentleman who was compelled to lead the life of a hermit, who was excluded from society by the exceedingly offensive smell which issued from the spaces between the toes. It was disagreeably perceptible the moment he entered a room; no amount of cleanliness or repeated ablutions dissipated the fœtid odour. Deodorizing applications of various kinds had been tried, and with only slight and temporary benefit. The treatment from which, as long as he remained under my observation, he appeared to derive advantage, was a daily tepid bath, a diet exclusively vegetable and farinaceous, and the frequent application between the toes of the following ointment:—

> Mercurial ointment, one ounce;
> Creasote, one drachm;
> Muriate of morphine, half a drachm.

He returned to thank me for the good he had derived from the treatment; but whether the cure was perfect and permanent, is more than I can affirm. Many cases I have seen of exaggerated natural effluvia from the spaces, or rather from the cutaneous follicles between the toes, but none so intense and distressing as that which I have just sketched. Those who feed largely on animal substances, and take little exercise, are apt to emit from the axillæ an offensive odour, and also from the mouth, fauces, and nares, so as to produce a most unpleasant impregnation of the breath. It is a curious fact that I have met with several monomaniacs in whom the solitary mental error which unyieldingly prevailed was, that a foul emanation, which in reality had no existence, rendered them unapproachable by any without disgust. I have exerted all my ingenuity without success to liberate the mind from this, as I found it, incorrigible error.

The cultivation of the sense of smell is oftentimes in diagnosis of considerable value. The mercurial fœtor is, by one whose perception of odours is both acute and educated, readily distinguishable from other fœtors, and often affords the earliest announcement that a course of mercury has been already carried sufficiently far, or at least that it is time to press it less energetically. The odour of the perspiration in miliary or sudatory fever at once bespeaks the nature of the disease. The exhalations from the breath and persons of those labouring under saccharine diabetes are often very characteristic. In every variety of bowel derangement and diarrhœa, the presence or absence of the specific feculent odour holds a by no means unimportant place amongst diagnostic signs. The same observation is applicable to many of the morbid conditions of the urine. Habitude and attention greatly improve the sense of smell, as they do the other senses so

valuable in diagnosis: how excellent soever they may be by nature, they will be greatly advanced in excellence by education. To the physician and to the surgeon, in many ways, an acute and experienced sense of touch renders clear and certain to the mind's eye what were otherwise obscure and doubtful; and by determining the diagnosis, determines the treatment. I need not adduce instances; they are obvious. The value of the sense of vision it were superfluous to dwell upon. Very much, indeed, of medical acumen and sagacity depends upon the innate powers and indefatigable culture of the observant and eagle eye. Of all the organs of sense, that which is most valuable in the detection of the seat and nature of invisible disease is the ear. The application of the sense of hearing to the diagnosis of invisible disease ranks amongst the most important discoveries, the greatest triumphs of modern science. Of this discovery the glory is entirely due to the immortal Laennec. Whilst medical science exists, his name will live in the grateful memory of mankind. The discoverer of auscultation has rendered the whole science of diagnosis more accurate, more conclusive, than it had ever before been. Nor is this accuracy limited to thoracic; it extends to abdominal and other affections. It is a great step in advance for medical science; it is one of the most important epochs in its history. It is an interesting fact that the late Dr. Perceval of this city was in the habit of applying his ear to the chest in cases of which palpitation was the prominent symptom; but he did not see the magnitude of the discovery, he did not follow it to its vast and legitimate results—he touched the cord, but its vibrations ceased. There is little reason to doubt that the coast of North America had been reached by a Danish skiff before the transcendent genius, indomitable perseverance, and lofty enthusiasm of Columbus accomplished one of the greatest feats the world's history can record. A discovery is no discovery unless its value and importance be also discovered, appreciated, and its results worked out. The application of an additional sense to the diagnosis of disease has, like the discovery of a new world, laid open a mine of immense wealth; and effectually and splendidly has it been worked by its immortal discoverer, and by his highly gifted countrymen and successors, amongst whom I may mention the names of Louis, Chaumel, Andral, &c. Ably have they followed in the footsteps of the discoverer of auscultation, and greatly have they enlarged the domain of medical science; and I may be permitted to add, that there is perhaps no part of the world in which auscultation, conjointly with pathology, therapeutics, and morbid anatomy, is cultivated with more zeal, energy, and success, than in this our city.

We find, then, that a naturally perceptive and well-educated ear enables us to judge of internal disease with surprising minuteness and accuracy: this were, however, impracticable without the aid of the other senses, and of the valuable and correcting information derived from morbid anatomy; all must coöperate. You may have remarked that I have substituted the word auricular for physical, now so universally adopted. I will tell you why I like it better: I prefer a term which embraces within its import every sign of disease of which the ear takes cognizance. It embraces percussion and auscultation, immediate, mediate, and remote. Before the time of Laennec great attention was given to, and great stress was laid upon all vocal as well as catarrhal sounds. Pertussis is recognized at once by the sound of the cough. In croup and laryngitis the vocal and catarrhal tones, at first hoarse, rough, and sonorous, then dwindling down into a suppressed and scarcely audible cough and whispering voice, and even into the extinction of the power of utterance, mark with certainty the changes which are hourly taking place along the course of the inflamed membrane. The cough of bronchitis is by its sound alone at its different stages distinguishable from that of pleuritis. The sound of the cavernous cough is peculiar, so are also the sounds of the purely spasmodic and hysterical coughs. The heart-sounds are sometimes audible at a distance of several inches from the thorax: all these, and many others, are signs which, without immediate or mediate auscultation, convey, through the ear, to the mind, a clear diagnostic perception. I use the word "auricular" for the purpose of placing it in its proper category, and in conjunction and coöperation with the other organs of sense, the fundamental sources of all our knowledge, that thus the term employed may embrace every sign, immediate, mediate, and remote, for the perception of which we are indebted to the special sense of hearing.

PROCEEDINGS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON.

REMOVAL OF THE OS CALCIS.

Mr. Gay showed a patient from whose foot he had about six months since taken the os calcis. For extensive and irreparable disease of that bone, the foot would, in former days, have been amputated. The case presented, however, shows that the functions of the foot are very slightly interfered with by the loss of so large and important an element of its structure; for, as may be seen, the man can walk, and he can climb a ladder, almost as well as he ever could, and his gait was not seriously affected by it in any way.

Mr. W. Cooke presented a

REMARKABLE SPECIMEN OF ANEURISM OF THE ARCH OF THE AORTA,

taken from an American who had died three days previously at the Royal Free Hospital. Mr. Cooke stated that he had been requested by his friend and colleague, Mr. Thomas Wakley—whose unavoidable absence he regretted—to exhibit this diseased aorta to the society, and in doing so to state a few of the circumstances connected with the case. It appeared that the patient was an emaciated tailor who had been sent over from America to this country for change of air, by Dr. Mott of New York, under the impression, according to the patient's statement, that he was suffering from secondary syphilis. On the 25th of September, when he presented himself at the Royal Free Hospital, it was discovered that he had the aneurism of which he died, and there were no symptoms indicative of secondary syphilis, unless the pain about the left shoulder and down the left arm could be so considered. The poor fellow was only in the hospital a week before the aneurism burst and he died, having during that week coughed up or vomited frequent portions of blood, sometimes amounting to as much as a pint. Mr. Wakley having satisfied himself that the disease was in the arch of the aorta, of course could render no operative assistance, and the treatment consisted simply of acids, acetate of lead, and opiates. There was a very distinct bruit in the aneurismal tumour, which was situated just behind the first bone of the sternum and between the first and second ribs, producing a bulging at this part. The pulsations in the tumour were perceptible to the eye. Sometimes, but not at others, the pulse could be felt in the left subclavian and radial arteries of the left arm. The stethoscope revealed no lung disease. In the post-mortem examination it appeared that the aneurism was situated at the bend of the arch just as it begins to descend, and would have held a small orange. The sac

was rent in two places, anteriorly and posteriorly, the former having adhesions to the sternum and pleura, and the latter opening itself into the cellular tissue surrounding the œsophagus, and into the œsophagus itself, by a circular ragged hole the size of a sixpence. Through this opening the blood had escaped into the mouth and stomach, which latter organ contained a pint of coagulated blood. The left subclavian artery was very nearly closed, even when the clot was removed from the tumour, and when present it doubtless would sometimes be entirely so. The clot itself was very large, and in a great measure organized. In the water which was used to wash the preparation, there was deposited a quantity of earthy matter. The rest of the artery did not appear to have any earthy deposits in it. The left ventricle was considerably hypertrophied. There were a few pleuritic adhesions, but the substance of both lungs was perfectly healthy, as were the rest of the organs. Mr. Cooke stated that he had only that afternoon been requested by Mr. Wakley to present this interesting morbid specimen to the society, and therefore would not offer any general observations upon the case, but leave the preparation on the table for the inspection of those gentlemen present who took an especial interest in diseases affecting the heart and arteries.

Dr. Murphy then read an address. He congratulated the society, that the difficulties in which they were involved were likely to be removed, the appeal which had been made to the members for pecuniary assistance having been warmly responded to. There were only eighteen dissentients in the whole list of the society. The property in Bolt-court was also let to an eligible tenant; so that their prosperity might be considered to be assured.

HOMŒOPATHIC QUACKERY—DR. MURPHY'S DEFENCE.

He next referred to the question of homœopathy, which, he said, had been considered with great anxiety by the Council, the result being, the submitting the resolutions respecting it, which were adopted by the fellows on the preceding night, one of which had reference to the course to be pursued by them, when, in ordinary professional intercourse, they are brought into contact with the professors of this new mode of practice. On this and on the other points, he said, under any other circumstances, it would be a work of supererogation for him to assure them, that he fully agreed with them; and that while he occupied that chair, he should endeavour to render these resolutions as efficient as possible (hear, hear). Dr. Murphy then referred to the accusations that had been made against him; and desired the fellows to pardon a slight digression, while he sought to correct the misrepresentations, and replied to charges, of which, were he guilty, he should resign the president's chair (hear, hear). To the first accusation, that he had met a homœopath in consultation, his answer, in the terms of the resolution, was, that he had never knowingly done so, and, more than that, that he never would. He had invariably refused when asked so to do. This reply he had already placed on record; but to another and equally serious one—that in a certain certificate he had assigned as a cause of disease that which could not be true: that if true, its only effect would be to injure the reputation of a most respectable practitioner, and that therefore he was bound to retract his words,—he had not yet given any public reply. He now stated, that his opinion had been most completely misunderstood and misrepresented. In giving it, he had no intention that it should injure the gentleman alluded to, which it could only do by straining it from its proper meaning. He would willingly have given that gentleman any explanation of that certificate necessary to exonerate him, but his correspondence showed that he did not desire it. It could only be by the most gross misrepresentation that that opinion could be made to indicate any want of skill, attention, or judgment, on the part of that practitioner; for it presumed that the placenta was morbid, that it was of necessity adherent, so that it could not be completely removed, and further, that the disease which rendered it so was the same that afterwards appeared. In this opinion he (Dr. Murphy) may have erred, from not having been made acquainted with all the facts of the case; but he trusted that, while admitting this, the society would discriminate between such an acknowledgment and an admission that his opinion was absolutely erroneous—that it could not possibly be true. In his correspondence on this subject, he had explained this his view of his opinion, and he still held that it was within the limits of truth. It was formed on the facts that had been placed before him, and if there were other facts which might change that opinion altogether, he had not received them. Whether his opinion were right or wrong, he did not think it conveyed any injurious imputation on any one's professional reputation. There was not, therefore, the slightest foundation for either of the charges against him. Dr. Murphy then expressed his opinion respecting homœopathy, and classed the professed homœopathists, mesmerists, and hydropathists, with the professed charlatan, who sells his cures under a thousand different disguises. With such men homœopathy becomes a form of quackery, the more dangerous because it assumes the garb of a science. The secret remedy vendor is far more harmless; the public, if they trust in him, do it with their eyes open; but the charlatan who entangles them in the intricacies of a pseudo-science, who bewilders them in the subtleties of the absurd dogma, "similia similibus curantur," and presents to them his infinitesimal dose as the ultimate result of his scientific inquiries, is calculated to do a much greater evil, just in proportion as the scientific garb he assumes is calculated to deceive even the judicious and the reflecting (cheers). Still he (Dr. Murphy) felt that such a stigma should not be affixed to a professional brother without just cause, as it would lead to an abuse as great as homœopathy itself. There may be some honest men in the profession anxious to obtain some valuable grains of wheat from the mass of chaff, and who therefore may order smaller doses than hitherto, and consequently may look like homœopathists. Great caution should be used in classing these with the others, as, so far from aiding in the suppression of homœopathy, he feared it would give it unexpected support, by the dogged resistance to an act of injustice, and its effects on the human mind. He would say for such men, who have been educated as ourselves, and who through life have observed the same honourable course, that it is neither just nor prudent to hold them up to public reprobation merely because they happen to order an unusually small dose of medicine. Stronger and more decided evidence of homœopathic dementia should be first obtained, such as an open acknowledgment of the principles of homœopathy as the foundation of their practice, and an admission that they are converts to these novel doctrines. Then is the time to act with decision and effect. In saying this, he did not wish to shelter the secret homœopathist, or to say that he should not be called upon to declare his faith, to make his election, but to caution the society against the abuse that may be made of its honest intentions. Professional character is the only property a professional man has; deprive him of that and you deprive him of everything. This being the case, the evidence against any one of our professional brethren should be of the clearest nature before he is singled out as an object for attack or accusation.

ACADEMY OF MEDICINE, PARIS.

M. Grisolle read, in his own name, and those of MM. Louis and Bricheteau, a report on a work by Doctor Dubreuilh of Bordeaux. M. Grisolle observed that he had, in 1849, presented a work which went to prove that pregnancy, so far from arresting the march of phthisis, tended to its precipitation; that labour and the puerperal state do not hasten the fatal termination, but prolong it, provided that the disease is not already far advanced. Dr. Dubreuilh's memoir furnished additional evidence in support of these opinions. In the thirteen observations collected by M. Dubreuilh, phthisis had been declared during the three first months of gestation. Four women had

been in good health at the time of conception, whilst eight others had presented more or less definite symptoms of disease for a long time before. Contrary to what would have been looked for on the ordinary view of these cases, the symptoms of phthisis, instead of improving, became more confirmed. In no case was the alleged suspensive power of pregnancy upon phthisis observed; on the contrary, it seemed always to perform the part of aggravating that malady. According to M. Grisolle, the cases are more common where the first signs of phthisis coincide with the commencement of gestation, than where pregnancy follows on the first symptoms of disease. Women in whom the development of phthisis is decided are less disposed to become pregnant. M. Dubreuilh had made the same observations. M. Delafond had also noted a similar fact in animals. Pregnancy does not modify the character of the phthisical disease. M. Dubreuilh states the opinion—in which, however, M. Grisolle does not concur—that in the last week of gestation pregnancy interrupts the progress of disease. Exceptional cases only are admitted by M. Grisolle. It is rarely, he remarks, that phthisis, complicated with pregnancy, offers those remissions or suspensions which occur in ordinary phthisis.

M. Dubreuilh has arrived at the conclusion that parturition and the puerperal state precipitate the termination of phthisis to a greater extent than is allowed by M. Grisolle, who asserts that, except where the disease is far advanced, and actual suspension of phthisis may follow on parturition.

Dr. Dubreuilh has observed that parturition is generally easy in phthisical patients; at the same time he states that lactation is attended with injury both to mother and child in the phthisical patient.

Dr. Alexis Favrot submitted an ingenious contrivance, which consisted of an empty bladder, to be introduced into the rectum, and when there to be distended with air from another bladder, connected externally by a tube and stop-cock to the former. By gradually filling the bladder in the rectum, the displacement, especially retroversion, is restored effectually, and without pain.

M. Champouillon gave the following results of his experiments—102 phthisical patients were treated with cod-liver oil. Of these, 51 were in the first stage; of which 21 were cured: 37 were in the second stage; of which 9 were cured; 3 died: 14 were in the third stage; of these 6 were cured; 4 died: 75 other phthisical cases were treated with iodated oil. In none of these did any amelioration take place: in many the disease was aggravated.

M. Malgaigne read a report on an essay by M. Parise, in which the author treated of the strangulation formed by a diverticulum having become twisted around one or more folds of the intestines. M. Parise pointed out two forms of this accident,—one in which a single fold of a diverticulum causes strangulation through its extremity becoming distended by gases, and thereby preventing its liberation. The second variety consisted in a double fold of a diverticulum around the intestine.

The appendices being situated at the lower part of the ileum, the author observed that these strangulations are generally to be found in the right iliac region. With regard to treatment, the author suggested the puncturing the end of the diverticulum as a means of relaxing the constriction after the performance of gastrotomy.

M. Monneret related a case of anæmia occurring in a young woman, aged 28, in whom the diseased condition had arrived at its worst. The debility was extreme; the decoloration of every part complete; and all the usual signs of a disordered circulation aggravated in the highest degree. Tonics and full diet were useless. The symptoms became worse and worse; syncope, vomiting, agitation; pulse imperceptible; incessant urgent thirst, &c. In short, the patient resembled a corpse and death seemed imminent.

M. Monneret very slowly injected about three pints of defibrinated blood—*i.e.*, the serosity and globules. The pulse rapidly rose, and became full. In about ten hours afterwards, however, the improvement vanished, and the patient sank rapidly.

M. Monneret proceeded to consider the question, whether the patient's rapid death was owing to the disease or to the transfusion. M. Monneret attributed the result to the progress of the anæmia; at the same time he observed that it must not be forgotten that the fluid injected was very different from living blood; that it was, in fact, the *cadaver* of normal blood; the foreign blood having but little relation to the vessels into which it was forced.—*Med. Gaz.*

POPLITEAL ANEURISM CURED BY COMPRESSION.

By James Allan, M.D.,
Deputy-Inspector of the Royal Naval Hospital, Haslar.

William J——, aged 27, a pensioner from the Royal Marines, was admitted, on the 10th October, 1848, into the Royal Naval Hospital at Haslar, by Admiralty order, with aneurism in the right popliteal space, about the size of the longitudinal section of a turkey's egg; the pulsation strong and bruit distinct. He stated that it had been gradually increasing for the last five weeks; he walked lame, suffering from pain and numbness of the leg and foot; had been employed as a labourer, and obliged to carry heavy weights frequently.

He was put upon low diet, his bowels freely opened, and the part occasionally looked at, until the 16th, when a flannel bandage was rolled from the toes to the groin, and a tourniquet applied, the pad resting on the artery about half an inch above the tumour. The pressure was only carried to the extent of making a slight impression upon the pulsation, and to give him little or no pain.

On the 19th, a second tourniquet was applied on the femoral artery, at the lower third of the thigh, and regulated so as to relieve the lower instrument. He then took the following pill three times daily:—Acetate of lead, half a grain; powder of opium, one-fourth of a grain,—made into a pill with extract of liquorice; and, at the same time, a draught of one drachm of distilled vinegar and one drachm of syrup of poppies, in an ounce of water.

On the 27th, a third tourniquet was applied, as nearly as possible below the giving off of the profunda, and the pressure regulated to ease the other two, but not to suppress the pulsation entirely. The process of cure was fully explained to the patient, and strict directions given to keep up such a degree of pressure as only to control the circulation, and not to give pain. He was seen frequently daily, and the nurse, an intelligent woman who had previously had the care of two cases successfully treated by compression, kept a watchful eye upon him, reporting every circumstance, and was obliged occasionally to call the medical officer on duty, to relieve the pressure when it had been carried too far. The bandages were removed daily, and the tourniquets shifted, so as to keep up a certain degree of pressure, and prevent the full impetus of the circulation into the tumour, which had been getting firmer and smaller since the 27th.

On the 4th of November, the pulsation being indistinct, the tourniquets were removed, to allow one of the medical officers to examine the part; and although only off for a few seconds, the pulsation returned in the upper part of the tumour, causing pain down the leg and in the foot, but which was in a short time relieved by the application of the bandage and tourniquets.

On the 8th, he complained of faintness, coldness about the heart, and pain in the stomach. The pills and draughts were omitted, and these feelings disappeared.

On the 10th, no pulsation could be felt in the tumour, from which date the pressure was gradually relaxed, until the 27th, when it was entirely removed, and friction with soap-liniment applied to the limb. The tumour was then solid, and several vessels were felt pulsating round the knee and sides of the limb.

On the 2nd of December, he was allowed to sit up; on the 8th, to walk about the grounds; and on the 29th, the tumour being almost entirely absorbed, and his health good, he was discharged cured.

Remarks.—This case is considered interesting, as, from the size of the tumour, and thinness of its parietes, treatment by compression was thought a very doubtful remedy.

Two of the tourniquets used were half-circles of iron, with a screw and pad at one end, and a flat splint at the other. The third was a forceps, with the pad and splint on the ends of the blades, the regulating screw passing through the opposite extremity of the instrument, the pressure being thus applied only over the artery, and the counter-pressure on the back of the limb, leaving the circulation otherwise uninterrupted.—*Lancet.*

The success of pressure in this case is decisive of its merits as a means of treating aneurism. The rude and imperfect instruments employed tested the practice severely. We would suggest that a set of the proper compressing apparatus should be sent to Haslar by those to whom such matters are entrusted.

ON IODOGNOSIS.

M. Dorvault has published a series of researches on the chemical, therapeutical, and medical properties of iodine. To these, as embracing the entire knowledge of all the properties of that substance, he has given the name of iodognosis. We submit an abstract of the medical portion of these researches from the *Gazette Médicale de Paris*:—Iodine, as a therapeutic agent, according to M. Dorvault, is unimportant; it is to its combination as *iodide* that its medical value is due. Even when introduced alone into the system its therapeutic effects are to be attributed to its combination with the alkalies which exist in the fluids of the body. Under either circumstances the terms *iodic medication* express the same fact. Iodide of potassium is taken by M. Dorvault as the type of iodides.

Physiological Action of Iodides.—Iodides belong to that class of therapeutic agents to which M. Dorvault gives the name of *chemico-catalytic*, and form its most striking representative. This proposition is founded on the following facts:—If the animal fluids (blood, lymph, semen, milk), or their proteic elements (albumen, fibrin, casein), be subjected to the action of a solution of iodide of potassium, it will be seen to prevent their coagulation and dissolve them. In producing this effect the salt remains unaltered; it acts, therefore, by virtue of what chemists have called the *catalytic* force. The same may be shown to have obtained when employed in certain pathological cases. The salt may be detected unaltered in the blood or urine, or other secretions.

These facts have been observed by many other investigators, and all have found practically that iodide of potassium promotes secretion, increases the functions of the mucous glands of the alimentary canal, and of the liver, kidneys, skin, pancreas, parotid, &c.

Iodide of potassium is rapidly eliminated from the animal fluids. Dr. Scharlau (of Stettin) found that a patient to whom he gave fifty-three grammes daily, eliminated fifty-one grains by his urine. The five grains lost were accounted for by the elimination of this salt by the saliva, sweat, and tears. Dr. Kramer satisfied himself, from his experiments, that six days sufficed for the complete elimination of this salt after its exhibition during fifty days. The researches of Dr. Marchal, at Vâl de Grace, also prove the rapid passage of iodide of potassium by the urine.

Iodine introduced into the system has been separated by the action of alkalies on the blood.

Special Action of Iodides.—The accidental or consecutive action of iodides has often been mistaken for their primary or efficient action. Some physiologists have considered iodine as a stimulant, others as a contra-stimulant. M. Dorvault observes that neither view expresses the exact truth. He admits a certain degree of general constitutional excitement under its employment; also that in severe pains of the bones, and other tumours, the action of iodide is sedative by allaying pain. But in both these cases the stimulation and the sedative action are the consequence, not the cause, of the beneficial therapeutic agency for the remedy.

A third opinion, that iodine is alterative, M. Dorvault regards as nearer the true explanation, but as insufficient in fact, as the medicinal influence of the iodides is often seen after the first dose, therein differing from alteratives. M. Dorvault admits, however, the alterative action of some substances in which iodine exists in minute quantities—*e.g.*, sponge, cod-liver oil, &c.

M. Dorvault also considers the purely chemical theory of the action of iodine as incorrect; his own opinion being, that the medicinal virtue of the iodides consists in their power of dissolving or further liquefying the *humours* of animal bodies, of separating their constituent or proteic elements, and disposing these to the formation of new products, such as coagula, false membranes, and pathological concretions: that the iodine and the potassium united both concur in the production of this result, by a special and peculiar chemico-physiological power which iodides possess of liquefying the fibrin of the blood without destroying the globules; while potash, ammonia, and other substances, dissolve the blood in all its parts.

Therapeutic Action of Iodine. The pathological states in which it is employed.—Goitre, scrofula, syphilis, skin diseases, white swelling, caries of the vertebræ, tapes mesenterica, rickets, phthisis, leucorrhœa, amenorrhœa and chlorosis, cancer, cachexies, dropsy, poisoning, tumours, rheumatism, various chronic diseases, hypertrophy. These are the forms of disease in which, M. Dorvault observes, the administration of iodine is indicated.—*Med. Gaz.*

GUTTA PERCHA—ITS USES TO THE PHYSICIAN AND SURGEON.

By John P. Little, M.D., Richmond City, U.S.

As this article is not as well known as it should be, I have put together some account of its uses and advantages, and of the manner in which it is wrought into various shapes. My wish is to call the attention of country physicians to the fact that it will save them much trouble if they possess and know how to use this excellent substance. It is a product of the East Indies—the dried juice of a tree; a tough, fibrous substance, of a dark brown colour. As it seems scarcely acted on by any other agent than heat, and as when heated it will take any form you give it; as it is very tough and strong, and is unaffected either by the temperature or by the secretions of the body, the physician will at once perceive its great value and the variety of uses to which it may be put. Of it are made splints, stethoscopes, bougies, catheters, uterine, and ear specula, stomach tubes, pessaries, handles for surgical instruments, caustic holders, tents, eye-glasses, sheets of waterproof stuff for dressing injuries, &c. &c. &c. The good sense of each physician will teach him how to make use of it in various cases. It will be found specially adapted to fracture occurring in children, to fractured jaw, or to injuries of joints.

To ascertain a good article, take a small piece, soften it by heat and roll it; if when cold it is tough and strong, the gutta is good; sometimes it breaks like a pipe-stem and is good for nothing.

To prepare it for use it should be cut into pieces and torn into strips, that impurities may be easily shaken out. Let it be then softened by boiling water, and rolled out in thin sheets. When these are dry, a stiff brush passed over them will sweep away the remaining impurities. The gutta should be then softened frequently and rolled together, its fibres mixed thoroughly, that it may become a homogeneous mass. In making catheters it is necessary to select the best gutta and prepare it with care; having well selected and well prepared the article, take a small piece; soften it, pierce it with a wire, and on this roll it carefully, softening it as it is needed; when it has thus obtained half the length and double the thickness of the catheter required, let it cool, and then, fastening one end to the tube securely, lay hold of the other with a pair of forceps and pull it out. It will be found that it can be

pulled out to twice its length and no farther, unless force enough be used to break it. Insert a wire of proper size, close one end by heat and make orifices; the catheter is complete. A polish may be put on it by passing it rapidly through the dry flame of a spirit lamp. This excellent catheter resists better than the gum elastic ones the action of urine, can be made of any size by the surgeon whenever it is needed, and does not cost more than half a cent in price of material. Some mix lampblack with the gutta, to render it less easily softened by heat; any mixture, however, makes it brittle. Flexible stethoscopes can be made in a similar manner. It is a peculiarity of gutta percha that when pulled out in this manner it becomes elastic; a property it had not before possessed. These are only some few uses to which it can be put; they are endless, and extend from serving to rub out lead pencil marks to making artificial palates. Out of the profession shoesoles, horsewhips, bridles, water-pipes, picture frames, &c. &c., are made with it.

Gutta percha resists cold and moderate heat; it is not acted on by the secretions; the acids and alkalies do not affect it, or but very slightly; iodine and nitras argenti do not alter it; æther and alcohol leave it untouched; only two substances dissolve it—chloroform and boiling turpentine, and of these solutions I will speak a few words. Forty grains of gutta percha dissolved in an ounce of chloroform make a reddish brown liquid, similar in properties to collodion, although not quite equal to it. I have applied it to sore nipples and to ulcers, over which it forms a transparent cuticle, protecting from external injuries and allowing the healing process to go on. It serves as a styptic to fresh cuts and to leech bites, and might be of use in chilblains, in preventing the effects of pressure forming bedsores, in protecting the heel from injurious pressure in cases of fracture, or perhaps in annoying eruptions, a covering of it would ally the irritation.

One use that I have put it to is, to protect surgical instruments from rusting. By dipping them into this solution they became coated with a thin pellicle of gutta percha, which protects them from air and moisture, and which can be easily rubbed off or wiped off when the instrument is used. It serves also as a covering for packages of vaccine matter; although the common gutta percha, rolled out and applied by heat, serves even better for such a purpose.

Another use is to render pills tasteless by dipping each one in this solution; the covering formed prevents the taste and does not hinder the effect of the medicine. Capsules could be formed of it for administering copaiva or other nauseous medicines.

The other solution is made by cutting up from half an ounce to an ounce of gutta percha and dropping it into a pint of boiling turpentine. It makes a good application to burns; the turpentine is of use in such cases, and the gutta would form a covering to the injured part. Waterproof paper is made by saturating it with this solution, and can be put to many uses. It serves a purpose similar to thin sheets of gutta in using water dressings; or, as oiled silk does, it will retain volatile stimulant applications to any part. As the strongest aqua ammoniæ has no effect on it, we can apply this powerful stimulant by simply pouring it on the paper and binding it tightly to the part. Opiates, turpentine, tincture cantharides, &c., can be thus applied and over large surfaces. The lower extremities can be wrapped up in sheets of this paper, or the whole chest stimulated by means of it; nervous headache, nauseated stomach, or any local pain can be similarly treated. Of course in applying it we should use moderate heat, that it may fit more closely. From its toughness and strength it will last a long time and serve for many applications. Another use of this turpentine solution is to brush it over anatomical preparations. It protects from air and moisture and also from the attacks of worms; or it may be used to cover bottles of alcohol containing wet preparations.

These are but some of the uses to which gutta percha can be put; its many valuable qualities and its easy applicability to various uses recommend it to the medical profession.—*The Stethoscope, Virginia, U.S.*

CLAY PIPE SWALLOWED AND PASSED PER ANUM.

M. Gosselin, a few days ago, brought before the Surgical Society of Paris the following extraordinary case:—A man, 30 years of age, of a pretty strong constitution, had of late made it a trade to swallow various objects for small remunerations. About two months ago he wagered that he would swallow a clay pipe; the latter was of the ordinary size, about three inches and a half in length; it had only been smoked four times, and contained no tobacco. The wager was taken, and the foolish man won it. He had no difficulty in swallowing the foreign body, but as soon as it had reached the stomach, severe pain was felt, and vomiting and diarrhœa came on.

The patient sought relief at the hospital of the town of St. Germain, but he obtained no relief during the fortnight he stayed in that institution. He was now advised to go to Paris, and was admitted at the Hôtel Dieu, where M. Gosselin tried in vain to put a stop to the vomiting and diarrhœa. The man was becoming very weak, and looked very much like a patient dying of phthisis; the tongue was red and dry, and the sickness recurred five or six times a day. M. Gosselin felt very much embarrassed. In consulting systematic writers, he found that Hevin had removed foreign bodies from the stomach by the operation of gastrotomy; but as to the method to be followed when the foreign substance is lying in the intestines, he discovered only a few precepts, but no facts.

By careful percussion with the plessimeter, dulness was discovered in the right iliac fossa over a space of about two or three inches; no gurgling or tumour was observable on the spot, and it was very probable that the pipe had reached that region. On the next morning this dulness had disappeared, and in the course of the same day the clay pipe was evacuated per anum, quite intact, with the tube unbroken. The system had, however, been very severely tried, and the patient sank five days after being freed from the foreign body. No trace of redness or congestion was found in the stomach or the small intestine, but in the colon numerous ulcerations were observed; some quite recent, and others completely or almost cicatrized. Membranous exudations covered the convex surface of the liver and the inferior aspect of the diaphragm. In the chest, traces of pleurisy and pneumonia were discovered.

Another 'Pathy.—In Naumberg a man named Mahner is preaching the necessity of a new regeneration, not in the spiritual, but physical sense. He warns a sickly race that it must return to the lost state of "primitive health," or *Urgesundheit*, as the means of more fully enjoying life and attaining a patriarchal old age. It is to be secured by a diet of bread and water, going barefoot, and letting the hair and beard grow; in short, making a nearer approach to man's original state in costume than the decencies or prejudices of modern society will altogether permit. On this topic he has been lecturing to a chosen few, but his doctrines do not seem to take, bread and water not being tempting, even with fourscore years promised as the prize of self-denial. It is also said that the apostle does not fully act up to his own precepts, preferring a well-spread table and every variety of wine or beer to the pure element; but this may be a calumny of the hotel-keepers. The German journals are perpetually turning up some eccentricity of this sort; to repair or preserve health, the oddest "cures" are resorted to. A section of the public seems determined to escape the hands of the faculty, and die by some irregular process, rather than with the aid of medicine. In a single advertising sheet could recently be counted up a water cure, a grape cure, a milk cure, and a hunger cure; to these must be added another just getting into vogue—some of the former having had their day—it is the cure by muscular exercise, by which cripples from rheumatism are put through a course of gymnastics; and dancing is prescribed for the gout. These, however, are all merely cures or remedies; the "primitive health" theory is founded on a system of living which would literally make "man's life as cheap as beasts," without much prolonging it. As far as hair and beard go, many of the Berliners are meeting the Naumberg preacher more than half way.

REMARKABLE RECOVERY FROM FRACTURED SKULL AND LOSS OF BRAIN.

By J. Snyder, M.D., of Romney, Hampshire County, U.S.

On the 15th of April, 1851, a son of Colonel Vaus Fox, aged 8, was run over by a horse and thrown violently upon a rock jutting out of the ground, which fractured the skull very extensively. About two hours after the occurrence of the accident I was called to the case, and upon examination found the injury to be at the middle portion of the temporal arch, between the parietal protuberance and frontal suture, implicating a portion of the frontal bone. A portion of the parietal bone, precisely one inch and a half in length, and of an elongated tringular form, was forced endwise into the middle lobe of the brain, penetrating its investing membranes and entering its substance. Parts of the parietal frontal and temporal bones were fractured into five or six pieces, making a comminuted, depressed space of four inches, which presented a perfectly concave appearance, with a wound in the centre of the depression about one inch in length. With the assistance of my friend, Dr. Pratt, after removing the hair, the wound was enlarged to the extent of one inch and three-quarters, to facilitate the extraction of a portion of the parietal bone completely hidden in the cerebral mass. After the wound was enlarged, I extracted the piece of bone with forceps, and removed about a dessertspoonful of the middle lobe of the brain, which followed its extraction and forced itself out of the wound. This done, the little fellow seemed to arouse up and regain his sensation—so much so as to make a considerable struggle and effort to rise, but was forced to remain quiet by assistants. The struggle caused a second protrusion of the brain, which being detached from the cerebral mass, as we supposed, was cut away with the surgeon's scissors. I then proceeded to raise with an elevator the depressed pieces of bone to their normal position, which was accomplished with considerable difficulty, being compelled to use a good deal of force. It was, however, accomplished satisfactorily, and the wound dressed with emp. adhæsiv. and a light compress, leaving a small space between the strips to permit the blood, &c., to escape. During the operation the little fellow was perfectly comatose, except for a moment immediately after the extraction of the bone. He was now placed in a well-ventilated and quiet apartment, closely watched, and under the constant surveillance of a doating mother. Although a very tractable and obedient child, yet it was necessary for those around him to watch him closely, as his position was frequently and abruptly changed from side to side with quick and sudden tossings, which made it necessary for his attendants to stand by to retain him in bed and to adjust the cover. He frequently placed his hands on the wounded part, but complained of very little pain. He was very closely watched during the night and next day by Dr. P. and myself; and on the following night, about thirty hours after the operation, reaction took place, which required for the protection of the brain three copious bleedings, about an hour apart. This free abstraction of blood had the desired effect of reducing arterial action and quieting the whole system.

On the following day it was thought best to excite the bowels to action, which was done by enemas, and subsequently by giving quarter minim doses of ol. c. tiglii mixed with bread crumbs, repeated every two hours until some effect was manifested. After this an occasional pill of the same was given, which, by one or two repetitions, always acted pleasantly. No further evidences of excitement manifested themselves during the progress of the case. The head was cleansed and dressed twice a day for a few days, and subsequently but once a day, and recovery was unexpectedly rapid, being three weeks before he was able to walk in his room, requiring no change of treatment; and the little fellow is now (August 10th) in robust health and fine spirits. As is usual in this character of injury, I feared the occurrence of fungus cerebri, but these unpleasant consequences have not shown themselves, and it is not probable that anything of the kind will arise, as it is now four months since the accident; and I feel confident his intellectual faculties have not sustained the slightest degree of injury. On the 16th of August, four months after the accident, he had an attack of scarlatina simplex, which passed off without an unpleasant symptom, and without any medical treatment other than a tepid bath and confinement to his room.

What is most remarkable in the above case is, that an injury so extensive, involving so much of the skull and a loss of so much of the cerebral mass, should recover so soon, and with so little medical assistance.—*Stethoscope.*

NON-UNION OF FRACTURE SUCCESSFULLY TREATED BY MERCURY.

By Mr. Thursfield of Broseley.

In the month of August, 1847, I was asked to see an old patient of mine, aged 42, who had twice suffered severely from acute rheumatism. I learnt from her that about eighteen weeks before, she had, on returning from an evening visit to her sister, slipped in crossing a rough road, and fractured both bones of the leg just above the ankle. She was not far from her sister's house, and a surgeon was soon in attendance. Her leg was placed on a pillow and the usual means employed; but in about six weeks after the accident it was ascertained that no bony union had taken place. Upon further advice starch bandages were applied but no benefit resulted. On examining the leg I found it greatly swollen, shorter by an inch at least than the other, with a good deal of deformity, greatly increased by any attempt at standing upon it, and the least motion at the point of fracture. She had greatly increased in bulk during the confinement she had undergone, but considered herself in good health.

I was a good deal puzzled what plan to pursue with the best chance of successfully relieving her, for I had never had to treat such a case before, and the uncertain results in the experience of others were anything but encouraging. In thinking over the case I remembered that the late Mr. Tyrrell had said mercury in his hands had proved at least as efficacious as any other plan he had tried; and I made up my mind to use it, because the peculiarly irritable state of the patient put sawing off the ends of the bone, seton, or any other surgical means quite out of the question, and most others seemed to have been fairly tried. I therefore procured two very strong gutta percha splints, which reached from rather above the knee to the bottom of the foot, and having, on the 18th, soaked them in boiling water, I made a complete cast of the leg by passing a tight roller over them and allowing them to cool. Having brought the ends of the bones as nearly into apposition as I could, and covered the parts with mercurial ointment, &c., after the plan recommended by Mr. John Scott, I applied the splint, and bound all together with a long elastic bandage. I confined her to bed, and tied the leg on a pillow, giving her five grains of blue pill night and morning. No perceptible effect from the mercury took place until she had taken sixteen pills, when suddenly violent ptyalism set in, which lasted a fortnight. On the 7th of October the bandages, &c., were removed, as they had become loose from the reduced size of the leg, and a great improvement was found to have taken place. The leg was longer, the deformity less, and the motion at the fracture scarcely perceptible. Greatly encouraged by such a state of things, I renewed the applications exactly as at first, and allowed her to use a sofa during the day. In about three weeks I again tightened the roller, and in another month removed everything from the leg, and found the fracture perfectly united and firm. For a month after this time she had the leg well rubbed night and morning with camphorated oil, to get rid of the remaining œdema, wearing a roller and one splint during the day, to protect the leg if she should chance to slip in walking. In six months she could walk well two or three miles, and is now as active as most women of her age, the broken leg being as useful as the other.—*Prov. Jour.*

TREATMENT OF SUBCUTANEOUS BURSÆ.

By W. Coulson, Esq.

The mode of treatment preferred by the author is simply puncturing the enlarged bursa with a grooved needle, such as is used for exploring tumours and swellings of doubtful character. After the evacuation of the contents, pressure is applied by means of soap plaster and bandage; this is renewed from time to time, and puncture of the sac repeated if necessary. The result is uniformly a permanent and safe cure. If to this we add the almost painless nature of the operation, we have, in this mode of treatment, all that is satisfactory to patient and surgeon.

When the large bursa becomes considerably inflamed, we should endeavour, by rest and other means, to subdue the inflammation. Nevertheless, a puncture such as has been described may be practised even in these cases with advantage to the patient.

Sometimes the integuments over the bursa ulcerates, and under these circumstances pressure may also be employed, as in cases of simple puncture. In cases of long standing, when the enlarged sac has put on the appearance of a sarcomatous tumour, excision is no doubt the remedy, having a due regard to the integuments.

No cases of enlarged bursa have attracted more attention than that of the great toe. The bursa situated on this part may become enlarged and painful, like any other superficial bursa, and require for its relief and cure the treatment recommended. But that which in a peculiar manner complicates the pathology of this enlarged bursa, is the accidental deformity caused by a projection inwards of the digital extremity of the first metatarsal bone. The phalanges of the great toe itself turn outwards to such an extent as to overlap, or pass under those of the second—a deformity, in fact, amounting to all but complete dislocation.

As the metatarsal bone recedes more and more from the second, the digital extremity seems to enlarge, causing a remarkable prominence inwards of this part of the foot.

In the meantime, as the deformity increases, the bursa is placed, daily, under pressure, more and more severe; the same shoe no longer fits the form of the foot, now much broader in the distal extremity of the metatarsal region; the bursa enlarges, and becomes extremely painful. A succession of bursæ form on the same spot; they open, and perhaps suppurate; and cases are stated to have occurred in which the joint itself has been laid open, and caustic applied to the inner projecting portion of the metatarsal bone, as if it were of morbid growth.

The disease, then, in its most aggravated form—that is, when complicated with this deformity—consists simply in an inflamed bursa, generally produced by pressure, with a partial dislocation of the great toe, mainly dependent on a displacement inwards of the digital end of the metatarsal bone. It will be sufficient to observe, that tight shoes, or rather shoes no longer fitting the altered form of the foot, however they may give rise to an enlargement of the bursa, in no case produce the deformity; for it is now universally admitted that the deformity is most frequently congenital, or comes on in very early life; that it occurs in hundreds who never wore shoes or boots, and that even, when present, it does not necessarily give rise to enlarged bursæ. The cases which most frequently come before the surgeon, occur in persons who get the deformity after the meridian of life. The deformity takes place as a result of the weakening of those structures binding together the metatarsal bones; the larger one recedes from the second, and the muscular forces, acting on the great toe, assist in adding to the deformity, by causing it to approach the others. The treatment of such complex cases is exceedingly difficult. It is here that rest, in the recumbent posture, becomes absolutely necessary; the inflammation must be subdued, or allowed to subside. Should a corn have formed on the enlarged bursa, it had better be cautiously pared down, as the skin has probably become much thinner over the bursa. When the foot has become tranquil, other questions arise as to the treatment, chiefly bearing on the form of the shoe; a boot, properly made of very soft leather, such as is worn in France, may be used without aggravating the complaint. Shoes are bad, as they necessitate a somewhat tight ligature over the instep; this causes intense pain immediately below it, or nearer to the toe. In time, the integuments may and do become accustomed to the form of the foot, and the bursa no longer enlarges. This is the ordinary course of events, even in cases by no means unfrequent, where the deformity has proceeded to its greatest extent. When the deformity is natural to the person, the bursæ do not naturally enlarge, and therefore give little or no trouble.—*London Jr. of Med.*

EXTRACTS FROM THE GULSTONIAN LECTURES ON DISEASES OF THE HEART.

By E. L. Ormerod, M.D.

1. *Symptomatic value of the Metallic Click (Metallic Cliquetis.)*—Occasionally there may be heard over the region of the heart a very peculiar sound, to which the name of metallic cliquetis has been applied. In the interpretation expressed by the use of the last appellation, both Hope and Bouillaud agree; and Hope gives some details explanatory of the mode in which the sound appears to him to be produced. Laennec explains the occurrence of this sound in the same way by costal percussion:—"When the heart, beating in a sharp and rapid manner, though without any really forcible impulse, the apex only comes to strike the walls of the chest." Now, obviously, this explanation is somewhat shaken by the fact that this peculiar sound (which there can be no question about, for any one may produce it quite pure for himself in the way specified by each of these observers) is not always audible at the apex in cases where it may be heard at the base of the heart. Dr. Hope correctly remarks that thin nervous persons are the most common subjects of it, but they are not exclusively so; and this fact again impairs the general applicability of the details of his explanation. The sound may be, and the author believes is, trivial, and almost wholly unimportant; but, for all that, we need not accept a wrong or an unduly limited explanation.

Dr. Ormerod has met with it under four different conditions. First, in nervous anæmic subjects, when the action of the heart was sharp; secondly, with more violent action of the heart, under circumstances which have led him erroneously to conclude, from the third condition with which he has less frequently found it connected, that it was indicative of the commencement of pericarditis. The fourth condition with which it has been found connected, is a rough, almost scaly, state of the pericardium about the base of the heart; and perhaps a fifth might be subjoined, but for the fact that it is not always constant under these circumstances—namely, adhesion of the pericardium, with which we may class the occurrence of this sound over an aneurism. Dr. Latham assures the author that he frequently meets with it in children, in whom he has noticed that it may be entirely suspended by a little pressure on the walls of the chest.

What should be the conclusion from these facts? The explanation by costal percussion is insufficient: it does not take in all the cases. The explanation by affection of the pericardium again is insufficient; certain it may be as far as it goes; yet there is positive proof, in the continuance of the sound after the two surfaces of the pericardium have become adherent, that the explanation does not go all the way. There are, then, three explanations of the mode of production of this sound—namely, costal percussion, friction of free surfaces, and movement of connecting areolar tissue. Each probably applies to a limited number of cases. There does not appear to be any one general explanation; nor, considering the nature of the sound, ought we perhaps to look for one.

2. *The Physiognomy of Cardiac Disease.*—There are few diseases but have their peculiar physiognomy. Among the many advantages resulting from the collection of vast masses of disease at our large hospitals, must be reckoned the opportunity thus afforded of learning rapidly to recognize the external characters, literally the features, of disease. Disease of the heart, too, stamps its peculiar marks on the face. It will not be superfluous to trace what Corvisart did not deem beneath his notice.

Many diseases communicate to the face an expression of their own, in which all distinctions of age are merged, and the child puts on the face of the old man. But it is not so with valvular disease of the heart. On the contrary, we

may readily, and without any forced refinement, distinguish between the features which childhood and more advanced age respectively assume under these circumstances.

In children suffering from valvular disease of the heart, the face and conjunctiva are pale and bloodless. Only, through the unusually transparent skin, small vessels may be seen ramifying over the malar eminences and the alæ of the nose, and the face becomes dusky on any exertion or emotion. The features are full, not pinched, as in most of the chronic diseases of childhood. There is no expression of anxiety. With the eyelids partly closed, and the eyes turned down, they sit motionless, save for the constant heaving of their chests, and even of their whole bodies, with the beating of their hearts. Sad experience has taught them which posture is the freest from suffering; and this they steadily maintain, either upright, with the head leaning a little forwards on the chest, or, as the disease advances, reclining back so as to extend the trachea to the utmost; doubtless on account of the relief which they thus afford to some labouring organ. They are sensible, and intelligent often to a remarkable degree, like other children who have suffered much from sickness, and seem to take pleasure in being auscultedand made objects of attention. But as soon as they are left to themselves, their eyes fix again upon some object, and they lie looking at it without apparently noticing it, like figures in wax.

The expression is quite different in persons of more advanced age: it is no longer one of placid quiet, but of anxiety and pain. There are still the same constrained unnatural postures, and the same fixed yet vacant gaze; but the face is drawn and livid, the lips are blue and pinched, the cheeks are of a dusky purple, and wherever the skin is put upon the stretch by subjacent parts, vessels may be seen ramifying just beneath the surface. Commonly, the skin hangs in a fold from the lower eyelid, so as to expose the dull dingy conjunctiva covering the sclerotic; bloodless, indeed, but wanting that pearly white which we see in anæmia. Much as bronchitis has to do with the sufferings of these patients, and with these particular appearances, yet attentive observation will recognize here quite a different expression to what we see in connexion with that disease. There is neither the intense restless agony of the present attack, nor the passive endurance when the acute stage of bronchitis is past. But to an expression which might suit with the most urgent distress and despair, there is joined a quietude of demeanour which might betoken perfect resignation. In all the patient's distress and uneasy movements, the great object of his efforts is to maintain the most complete rest; as if it were a question whether to bear the present posture, or the wearying search after one more tolerable to his feelings, were the greatest misery. He cannot be at rest, for rest brings him no relief; he seeks but in one to be freed from the feeling of another pain.—*Med. Gaz.*

TREATMENT OF VARICOCELE BY GUTTA PERCHA DISSOLVED IN CHLOROFORM.

By H. G. Carey, M.D., of Dayton, Ohio.

After having used gutta percha considerably for other purposes, a knowledge of its properties forcibly suggested it in solution, as admirably fitted to fill the desired objects sought in the treatment of varicocele. In order to apply it, the patient is placed upon his back, and by means of cold, the scrotum is corrugated until it is drawn firmly over the root of the penis, compressing the testes firmly in the upper portion of the inguinal pouches; then, by means of a camel's hair pencil, after the hair has been removed, apply the solution freely over the site of the scrotum, allowing it to extend on all sides some distance by a thin attachment: but over the scrotum proper lay on a succession of coats, until a uniform covering throughout of a line in thickness is obtained, which will be sufficiently strong to form an artificial pouch of the nature and character desired. This thickness will be so yielding and pliable, as not to afford the wearer any considerable inconvenience. Soon after the solution is applied to this *sensitive part*, the patient will complain bitterly of the burning sensation experienced, depending upon the presence of the chloroform; but this temporary inconvenience will soon pass off. The constitutional indications, if there be any, must not of course be neglected. I have not as yet had an opportunity to test the powers of this article in relieving the same condition of the veins in the extremities, but surely think that much pain might be prevented, and success in the treatment greatly increased.—*Western Lancet, U.S.*

REVIEWS AND NOTICES OF BOOKS.

ON DISEASES OF THE MUCOUS MEMBRANE OF THE THROAT, AND THEIR TREATMENT BY TOPICAL MEDICATION. By Wm. R. Wagstaff, M.A., M.D., Fellow of the Medical Society of London. London. 1851. Small 8vo. pp. 183.

The subject of the treatment of diseases of the throat by topical medication, has (the author states) occupied his attention for nearly six years; and in the volume before us "he has endeavoured to present to the profession a concise statement of the practical conclusions which he has drawn from an extensive experience during the whole of this period."

Dr. Wagstaff commences by giving a short outline of the anatomy of the throat, its mucous membrane, mucous follicles, and the tonsils; the diseased states in which local applications are most likely to prove beneficial are next considered; followed by a description of his mode of using topical applications.

The instruments the author uses for applying liquids to the laryngeal mucous membrane are, "a bent spatula and a whalebone probang, curved to various angles to suit the different conformations of the mouth, to the end of which a small rounded piece of fine sponge is attached."

"The method of employing these is to carry the end of the spatula to the lingual base of the epiglottis; then, by pressing the tongue firmly down, and drawing it forward from the base with the instrument, the laryngeal surface of the epiglottis may be exposed; when this organ is brought fairly in view, the great difficulty of the operation is overcome, for it only remains to direct the patient *to inspire* gently, and to pass the sponge of the probang to the posterior face of the epiglottis, and by a rapid motion to press it *downward and forward*, in order to introduce it into the larynx. Considerable skill in the manipulation is requisite to ensure success, and this can only be acquired by constant practice, united with an accurate knowledge of the anatomical relations of the parts.

Two points should be always remembered in the performance of this operation—first, that the epiglottis must be exposed; and second, that the end of the probang should be pressed *forward* as well as downward. With a careful attention to these directions, a skilful manipulation can scarcely fail to obtain an entrance into the larynx: yet this result must not be expected upon the first trial with any patient: nor, indeed, will it be prudent to attempt the application until after the pharynx and top of the larynx have become somewhat accustomed to the presence of the sponge and the medicinal agent with which it is saturated. Unless the character of the disease is of that urgent nature that will not permit delay, as in membranaceous croup, or any other acute inflammation of the parts."

In chronic affections less difficulty will be experienced (Dr. Wagstaff observes) by the operator, and far less pain given to the patient, "if two or three applications, at intervals of a day, are made to the fauces, pharynx, and epiglottis, before the introduction of the sponge into the larynx is attempted." The author states that he has found by experience "that the instrument may be brought in contact with the laryngeal surface of the epiglottis without producing any spasm of the glottis or surrounding parts; but that the moment it touches either the pillars or the pharynx, a retching action, more or less violent, is produced, by which the larynx is elevated to a contact with the epiglottis, and thus the possibility of entering it is for a time entirely precluded."

The substances which the author employs are the per-chlor. hydrarg., the bicyanid. hydrarg., the nitras hydrarg., the nitras potass., the sulphas cupri, and the nitras argenti (cryst.); he prefers the nitrate of silver, "on account of its rapid action, its efficacy, and its harmlessness." He uses solutions of various strengths, ranging from one scruple up to one drachm and a half, to the ounce of distilled water, and he prefers "the nitrate of silver in crystals to the anhydrous rolls, for its greater solubility, the clearer solution it produces, and its more certain purity."

"If the disease be in its early stage, and the irritation confined to small patches of the mucous membrane, it will be sufficient to employ a comparatively weak solution of the crystallized nitrate of silver consisting of twenty grains to the ounce of distilled water. With this the tonsils, pharynx, and epiglottis should be effectually sponged once a day. In the event of the disease continuing to spread over other and larger portions of the membrane, after these medications have been employed, the strength of the solution should be increased progressively at each application, until sixty or even eighty grains to the ounce is reached. When a hard frequent cough occurs, accompanied by hoarseness and pain, or impaired power on speaking, then the topical medication should be extended to the cavity of the larynx, so soon as the parts leading to it can be sufficiently accustomed to the presence of the sponge to allow its insertion, without difficulty to the operator or danger to the patient."

The "sequelæ" of catarrh are next considered—viz., "hypertrophy of the mucous membrane and enlargement and hypertrophy of the follicles or muciperous glands;" and the advantages of topical medication pointed out. The seventh chapter is devoted to "Inflammation of the pharyngo-laryngeal membrane and its muciperous glands" and their treatment."

Exudative inflammation of the mucous membrane of the throat, or croup, is considered in the next chapter. Dr. Wagstaff states that he has employed topical medication in almost every variety and stage of this disease, and with the greatest advantage. In "topical medication consists (he observes) my main reliance for the cure of true membranaceous croup, and in my estimation no other remedy whatever is required when the disease is detected in its catarrhal or early inflammatory stage." "I am convinced (the author adds) that I have again and again prevented attacks of exudative inflammation of the air-passages in children, by applications of the solution of nitrate of silver to the fauces and pharynx, whilst the mucous membrane of these parts was in that state of catarrhal irritation which almost invariably ushers in an attack of membranaceous croup."

The ninth chapter is devoted to the enlarged tonsil, and to elongation and enlargement of the uvula. The following are some of the author's remarks under the latter head, with which we must conclude:—

"A relaxed state of the uvula may accompany simple or acute catarrh, which will disappear upon the subsidence of the affection; but when the effusion and elongation have resulted from chronic catarrh, and have been present for any considerable length of time, Nature will not often be able, unaided, to restore the organ to a normal state.

This pendulous body, when morbidly elongated, will create an irritation of the pharyngo-laryngeal membrane and an annoying cough by its contact with the epiglottis and the pharynx."

The treatment recommended by the author consists in the application of astringents in the first instance; if these fail, he advises that a portion of the uvula be removed:—

"I am satisfied that the complete truncating of the organ is an operation which should never be performed when no other indication demands it than chronic elongation. For the irritation and inconvenience arising from this condition of the uvula, are produced only by its contact with the pharynx and epiglottis; and this mechanical irritant will be completely removed by the excision of so much of the diseased organ as will reduce its length to that of the healthy uvula. Nor do I know what argument can be used to justify the operation of truncating the uvula when no other disease is present than chronic elongation. As the muciperous glands, which are very frequently the cause of a continual irritation in the mucous membrane of the uvula, are situated mainly at its extremity, the removal of a portion of it will necessarily involve a removal of them; and thus all the advantages which can be derived from truncating the uvula may be obtained with equal certainty from an excision of a portion of it.

Some advantage will be gained, I think, by excising the organ with a bistoury, cutting in an oblique direction from behind forward and downward, so as to have that part of the extremity of the stump, which is rubbed by the food in its passage to the œsophagus, covered by mucous membrane. This method does not require more time than excision with a pair of scissors, and is attended with none of the objections which are made by some surgeons to the crushing action of that instrument."

FEVER HOSPITAL REPORTS.

ANNUAL REPORT OF THE ROSCREA FEVER HOSPITAL FOR 1851.

The number of subscribers' patients admitted into the Roscrea Fever Hospital, commencing the 1st of October, 1850, and ending the 30th of September, 1851, was as follows:—Remained 30th of September, 1850, 5; admitted from 30th of September, 1850, to 1st of October, 1851, 64. Total, 69.

Discharged cured, 62; died, 5; remain 30th of September, 1851, 2. Total, 69.

The number of pauper patients admitted within the above period of one year from the union workhouse and from the electoral divisions of the union on the relieving officers' tickets, are as follow:—Remained 30th of September, 1850, 108; admitted from 30th of September, 1850, to the 1st October, 1851, 1263. Total, 1371.

Discharged cured, 1200; died, 112; remain the 30th of September, 1851, 59. Total, 1371. Total number of patients treated within twelve months, 1440.

Expense of union fever patients from 30th of September, 1850, to the 1st October, 1851, £552 19s. 7*d.*; amounting to the average cost of 4½*d.* per head per day, *including all charges*. Average cost of *each* patient while in the fever hospital, 8s. 5½*d.* Average number of days *each* patient remained in the fever hospital, 24½ days. Average number of deaths, 8½ per cent. Daily average number of patients in hospital about 100. Number discharged, 1312.

DUBLIN: WEDNESDAY, NOVEMBER 12, 1851.

VALUE OF MEDICAL DEGREES.

Passing events and prospects of the future have set men's minds to work in the investigation of all matters pertaining to medical policy, and amongst them of the value of University Medical Degrees: whether that value be intrinsic or legal. The extracts we append below show how the subject is treated at the other side of the water, and it is our business to handle it on this. The mischievous licence so freely conceded to unqualified persons to practise medicine has led to a misconception, almost universal, respecting the true force and value of medical degrees. Not only does the world at large believe them to be licences or authorities to practise the healing art, but also do the heads of Universities flatter themselves that they are so. Nothing of the kind, however, is farther from the true state of the case. Medical Degrees are but honorary distinctions, no more conferring a right to practise medicine than do degrees in law cause men to be called to the bar, or degrees in divinity qualify them for ordination. At a remote period, and when perhaps they were better evidence of the graduate's knowledge or ability than they now are, they were accepted as a guarantee of qualification, but so inadequate did they prove as a security against dangerous pretenders, that speedily special charters and statutes were contrived to arrest their circulation, and to substitute for them a proper testimonial of professional fitness in the shape of collegiate licences issued by authorities exclusively medical. Indeed, at a very early period of their existence, they became as worthless as they now are in many instances, of which the anecdote of Rabelais procuring one for his horse, under the title of "Dominus

Caballus," affords proof. It could, in fact, scarcely be otherwise, seeing that they were, as they are even at present amongst ourselves, granted by ecclesiastics, fortified by a corps of professors adjusting their distribution to their own financial necessities. We are aware that many of our brethren, both in town and country, have paid for these expensive decorations (as indeed we have done ourselves, little to our advantage) ; but we run the risk of questioning their claims to substantial value; knowing that almost all have other proofs to produce of a right to undertake the treatment of disease. Even assuming that individuals may feel mortified by the insinuation that a long-cherished distinction is not of so much value as heretofore, we venture to hope that even they will see the necessity of making some sacrifice to avert the disgrace and ruin which threatens our profession in this country from the influx of medical mongrels. Time flies, and before men are aware that any change has taken place, they may find themselves hustled out of their places by a new race of "medical men" of university manufacture, half doctor half surgeon ; who, in vulgar parlance, may be designated as "jacks of all trades and masters of none." It matters little to those liable to suffer from questionable expedients, whether they are adopted from an imperative necessity or not. University professors, finding their "certificates" at a discount, may naturally enough attempt to rig the market with a new species of stock in the shape of diplomas; but as the frogs have it in the fable, "what is sport to them is death to us." No: every attempt to repair a rotten fabric with rotten materials should be discountenanced, seeing that the old house as it tumbles is liable to pull down new ones along with it; and so also should attempts to erect new buildings with equally faulty materials be prevented. If either the University of Queen Bess or the University of Queen Victoria can find no better means of perpetuating or creating a claim to public sympathy than by the manufacture of medical doctors or medical surgeons, the sooner they are deprived of such a resource the better; if for no other reason, for the purpose of proving, that as universities they are wanted as essential members of the body politic. The people want education, and the profession want educated young men to receive professional instruction ; to supply which is the obvious mission of these corporations. For the life of us we cannot discover what possible connexion there is between the teaching of Greek and Latin and the teaching of medicine and surgery. The very notion of seven learned Clerks sitting in Trinity College, or a score of Diplomatists, Lawyers, Divines, and Engineers, civil and military, in Dublin Castle, to test the fitness of medical practitioners, taxes our powers of restraint over our risibilities. It is downright ludicrous. Once for all, without fear of contradiction, we assert that medical and surgical education is the province of the Colleges of Physicians and Surgeons, and that at this hour of the day the universities should have nothing whatever to do with it. Moreover, we venture to suggest to the conductors of these universities, that the sooner they adopt this view the better, for time has stamped it with its approbation. The handwriting is on the wall, and let not the Fellows of Trinity College avert their heads, and pretend not to see it. Eight students only graduated as Bachelors of Medicine this year, at a cost of a thousand pounds and more, paid in salaries and allowances to their medical professors. At the Castle it is the same. Seven precious souls are sent on the same mission at an expense of another thousand; while in Edinburgh, one Irishman bends beneath the three-cornered cap of the Reverend Principal. Is not this what the politicians call "an accomplished fact;" and yet in the face of it do they hope not only to contend with it, but to build a castle upon its foundation. But we wander from our text, which it is our custom to have at the end of our discourse instead of the beginning, as some do their mustard after their meat. Here are the extracts we alluded to above:—

Dr. F. Hawkins says:—"You are aware, as well as myself, that there are no *legal* physicians in England and Wales, except the graduates of Oxford and Cambridge, licensed to practise, and the licentiates, and extra-licentiates of the College of Physicians. More than half, then, of the physicians to provincial hospitals have no legal title to practise as such in England."

Now, sir, I entirely deny the correctness of this assertion. And first let me ask—Who are the physicians of this country? Are they confined to the 671 fellows, licentiates, and extra-licentiates of the London College of Physicians?—to the 117 members of the Dublin College of Physicians (Parliamentary Evidence)? or to the still smaller number (I believe) of the Edinburgh College? Who were the physicians in Scotland before the establishment of their college? Who are now the physicians of France, where there is no college of physicians? How are the 25,000 practitioners of the united kingdom to be designated? Are they differently taught? Are they not examined on the same subjects? and do they not use the same means of cure?

Having, I hope, settled this matter to the satisfaction of every unprejudiced person, I go to the *legal* part of the question; and I assert, that a member of the Apothecaries' Company has as much legal right to practise as a physician, in any part of England south of the Tweed, as Dr. Hawkins himself. His *diploma* gives him this right; and if he choose to write a prescription, and take a fee of five guineas instead of one, there is no law to prevent him. The action brought by the College of Physicians, in 1828, against Dr. Harrison, a graduate of Edinburgh, would have been given in favour of the college if Dr. Harrison had not shifted his plea; but Dr. Harrison had no *legal* right to practise medicine in England, although he had passed a better examination than his persecutors. Such is the absurd and unjust state of the law in 1851. But to bring the matter to a *practical* test. I practise as a physician, and my only *legal* qualification is the diploma of the Apothecaries' Company. My University degree and my College of Surgeon's diploma give me no *legal* right to practise medicine. I defy this college to the trial. I will supply them with evidence; and promise them that I will resort to no legal subterfuge to defend my right. As a matter of policy, I admit the necessity of a man being a member of this college if he practise in London, as most public appointments are shut out from him, but I am anxious to let those of my professional brethren who are attached to provincial hospitals, and who are graduates of universities, know, that if they are members of the Apothecaries' Company, they are not practising, as Dr. Hawkins asserts, *illegally*. I speak of the *law*, not of the *justice* of the case. —*Letter in Lancet.*

It would seem that in England it is a matter of insuperable difficulty to trace the limits by which, in medical affairs, liberty is separated from licence. In France, however, the enforcement of a wholesome restriction is not regarded as tyranny; and certainly no European people know better than Frenchmen what is tyranny. In London it is thought wise that no let or hindrance should be presented to the adoption of any pseudo-medical practice by any individual, whatever may have been his previous pursuits or deficiencies of education. Thus, a grocer has been allowed to administer the most potent drugs with impunity, although a fatal result followed his rashness. In Paris quite another view is taken of such recklessness and presumption. Within the last few weeks the Parisian tribunals have inflicted heavy fines and long imprisonment upon persons who dared only to vend drugs without a licence in pharmacy. In England it was with much difficulty that a law was obtained to restrain the indiscriminate sale of one common poison; and even now it is a rare thing to procure conviction from a jury for the infringement of that law. In Paris punishment is summarily executed upon those who venture to sell poisons of any kind
